The production process of triticale in farms specializing in field crops was carried out in a way that ensured a full environmental efficiency compared to the milk and pig farming types. The group of milk farms was characterized by the lowest environmental efficiency (0.774). It would be possible to achieve a full environmental efficiency of triticale production, provided that the value of emission factors has been improved by an average of 22.6 percentage points. Generally, lower values of environmental efficiency coefficients for triticale production in farms with milking cows and also with pigs suggest that the conditions for achieving a full environmental efficiency are more difficult to meet by them than managing the costs of triticale production ensuring a better cost efficiency. The results also indicate that animal farms use nitrogen less economically by possibly applying excessive amounts of nitrogen to triticale fields and that they use larger amounts of pesticides, compared to the field crops farms. Animal farms have available manure which is utilised for fertilizing different crops, including also winter triticale, leading often to nitrogen balance surpluses that contribute to its excessive emissions to the environment (Bieńkowski and Jankowiak, 2006).

Table 1. Cost and environmental efficiency of winter triticale production according to the groups of economic size.

Specification	Economic size group (thous. Euro)			
	I (38,0)	II (38,1 – 96,0)	III (96,1 – 185,6)	IV (> 185,6 ha)
Cost efficiency	0.895	0.862	0.770	0.844
Environmental efficiency	0.782	0.817	0.798	0.763

*Source: Author's own calculation

The factor determining the diversification of cost and environmental efficiencies of triticale production was also the economic size of farms, calculated on the basis of the standard output value, expressed in Euro, (Commission ..., 2008). Table 1 shows the efficiency coefficients for separate farm groups of different economic size. The boundaries for division into four groups were determined by standard output, grouping 25% of farms ranked in order of increasing their output values. The farms in the first two groups achieved the highest cost efficiency coefficients for the triticale production. The difference in cost efficiency between the 1st and 3rd size group with the lowest cost efficiency was 12.5 percentage points. In turn, higher environmental efficiency was found to be concentrated in the middle size groups (2nd and 3rd). The results presented show that in smaller farms it is relatively easier to obtain better cost efficiency than the environmental efficiency. The largest farms showing inferior performance with regard to environmental efficiency of triticale production should take into account the introduction of technological changes optimizing a better utilisation of nitrogen fertilizers and plant protection products in relation to their production effects.

Conclusions

Farms specializing in milk production achieved the highest cost efficiency of winter triticale production, and at the same time they had the lowest environmental efficiency. Opposed values of efficiency coefficients had field crops farms in which the production of triticale was characterized by the highest environmental efficiency and the lowest cost efficiency. Milk farms should modify their activity to become more efficient by rationalizing their operations which limit the amount of nitrate available for runoff in fields with triticale. Second way of environmental efficiency changes in milk farms should be focused on decreasing the use of plant protection products contributing to lower emissions of active substances to environment. For the field crops farms, the preferential direction of changes in the triticale production should be the reduction of costs. The results of the research indicate that an important challenge for increasing the eco-efficiency of winter triticale cultivation may be the implementation of the environment-friendly farming practices and minimizing the production costs in different farming types .

Abstract

The effects of long-term (>20 yr) grazing on the selected physical properties of a non carbonated silty-clay Fluvisols were studied in the region of the Kolubara Valley, Northwest Serbia. Two adjacent land-use types (native deciduous forest and natural pasture soils converted from forests for more than 20 years) were chosen for the study. Disturbed and undisturbed soil samples were collected from three sites at each of the two different land-use types from the depths of 0–15, 15–30 and 30–45 cm. In relation to the soil under native forest, soil organic matter content, total porosity and air-filled porosity were significantly reduced after long-term of grazing. The bulk density (0.99–1.48 g cm^{-3}) and the saturated hydraulic conductivity ($6.9 \cdot 10^{-2}$–$3.2 \cdot 10^{-4}$ cm s^{-1}) were significantly lower in forest compared to the adjacent pasture (ex-forest) soil (1.49–1.55 g cm^{-3} and $3.4 \cdot 10^{-4}$–$5.5 \cdot 10^{-4}$ cm s^{-1}, respectively). In addition, forest had significantly lower dry mean weight diameter (7.0–9.2 mm) and greater wet mean weight diameter (2.0–2.6 mm) for 0–45 cm depth compared with the pasture (8.8–9.4 mm and 1.8–2.3 mm, respectively). The decrease of soil organic matter content and reduction in aggregate stability under long-term grazing rendered the soil more susceptible to compaction. In conclusion, the results of this study indicate that removal of permanent vegetation in the conversion process from forest areas to pasture land may lead to loss of soil productivity and serious soil degradation. Obviously, there is a need for greater attention to developing sustainable land use practices in management of these ecosystems to prevent further degradation of pasture soils in the region.

Keywords: *Pasture, Trampling, Soil structure, Hydraulic conductivity, Total and air-filled porosity.*

Introduction

It is known that grazing can affect soil physical properties. Changes to soil physical properties caused by grazing animals have received little attention compared with of arable soils (Greenwood and McKenzie, 2001). The longer-term effects of livestock grazing on soil physical properties are complex. According to Sharrow (2007), they reflect the balance of restorative and compactive processes at work on grazed and ungrazed areas. The actual impact of change depends on several factors such as the type of pasture ecosystem, soil type, mineralogy, texture, soil depth, initial soil properties, the nature, duration and intensity of the grazing, animal species and age, stocking density and management practices (Willatt and Pullar, 1983; Sparling *et al.*, 2000; Sharrow, 2007; Bormann and Klaassen, 2008; Reszkowska *et al.*, 2011), and long-term site-specific factors (e.g. parent material, topography and climate – Ogle *et al.*, 2005; Khormali *et al.*, 2009).

The conversion of natural forest into pasture is known to deteriorate soil properties, especially reduce SOC and change the soil structure (Yong-Zhong *et al*., 2005; Reszkowska *et al*., 2011). Grazing affects the grassland environment by a reduced vegetation cover followed by decrease in SOM content in the topsoil (Yong-Zhong *et al*. 2005). Due to shearing intensive grazing animals leads to rearrangement of soil particles as well as to soil homogenization (Drewry, 2006). Thus, animal trampling results in an increase in soil bulk density and hardness, decrease in pore continuity, reduction in soil porosity, hydraulic and air conductivity (Horn, 1986; Sharrow, 2007; Reszkowska *et al*., 2011). According to Greenwood and McKenzie (2001), the stresses exerted by livestock have similar influence on soil as agricultural machinery, however, due to smaller contact area, the soil deformation restricts only to the upper 15 cm soil layer. This zone is very important in determining soil hydrology and plant growth/vigor.

It is not clear from the literature whether heavy grazing leads to a deterioration of physical parameters of topsoils in steppe ecosystems (Steffens *et al*., 2008). In contrast, Lu *et al*. (2015) reported that short-term grazing exclusion has no impact on soil properties of degraded alpine grassland in Tibet, Chine.

The main purpose of our work was to evaluate the long-term (>20 yr) effects of grazing on soil quality by measuring the differences in the SOM and some physical properties of noncarbonated silty clay Fluvisol in the lowland ecosystems of Western Serbia.

Materials and Methods

Site description

The study was conducted in the Kolubara Valley in northwest Serbia (44°36′ N and 20°17′ E), in spring 2016. The area has continental climate, with a mean annual precipitation of 730 mm and a mean annual air temperature around 11°C. The area is geomorphologically plain and nearly flat. The soil was noncarbonate Fluvisols (FAO, 2006), developed on a poorly carbonated alluvium of the Kolubara River. The textural classes of soils at the 0–45 cm depth are: silty clay with 5.4–5.8% sand, 44.9–46.1% silt, and 48.2–49.7% clay for the forest; silty clay with 7.6–7.7% sand, 49.6–50.5% silt, and 41.8–42.5% clay for the pasture. More detailed information on the study area is presented by Gajić (2013). Three locations were selected in the Central Kolubara River Basin. At each location, sites of forest and pasture land were selected in close proximity (at a distance of ≈75 m) and of similar topography. The natural vegetation of the deciduous forest sites is characterized by a community of common oak and common ash (*As. Querceto-raxinetum serbicum, Rud*.). In the pasture, in addition to the grasses (*Festuca ovina* and *Poa pratensis), Ranunculus* and *Lathyrus* sp. were also dominating herbs. The pasture has been used over the last 20 years for grazing animals. The pasture was traditionally grazed by ewe and cattle around the 20 year. Stocking rates for the experiments ranged from 5 to 8 ewes ha^{-1} and 2–3 cattle ha^{-1}.

Soil sampling

Six sites were sampled, three within each of the two adjacent land-use types of forest and pasture. For each land-use type and its three sites, one monolithic (about 20 cm×15 cm×10 cm) soil sample of ≈ 4 kg was taken for each of the depth ranges of 0–15, 15–30, and 30–45 cm. These soils were collected to determine organic carbon (SOC), particle density, particle size distribution, wilting point, dry mean weight diameter (dMWD) and wet mean weight diameter (wMWD). To determine bulk density (BD), total porosity (TP), field capacity (FC) and saturated hydraulic conductivity five soil cores from each depth were collected using a 100 cm^3 cylindrical steel sampler (height 5.1 cm, and inner diameter 5.0 cm).

Soil chemical and physical analyses

In the laboratory, the monoliths were carefully broken up by hand along natural planes of weakness into aggregates of < 25 mm. After visible plant materials were removed, all soil samples were air-dried and ground to pass 2 mm sieve for the following measurements.
Soil organic carbon (SOC) concentration was determined using the dichromate method (Rowell, 1997). Particle-size distribution of the soils was determined by combining sieving and the pipette methods (Rowell, 1997). Bulk density was determined using the core procedure (Rowell, 1997). Particle density was measured with a pycnometer (Rowell, 1997). Total porosity (TP) was calculated using dry bulk density and a particle density. To obtain the water stored at field capacity (FC) and wilting point (WP), all undisturbed soil samples were saturated and equilibrated to a matric potential of −33 kPa using ceramic porous plates and to matric potential of −1,500 kPa using the pressure method, respectively (Schlichting *et al*., 1995; Hartge and Horn, 2009). The air capacity (AC) was defined as difference between TP and FC. The plant available water (PAW) was calculated from the difference between volumetric water content at FC and WP. The dry mean weight diameter (dMWD) and wet mean weight diameter (wMWD) as indices of soil aggregation were determined by the procedure outlined in Gajić et al. (2010). Saturated hydraulic conductivity was measured by the falling-head method according to Klute and Dirksen (1986). Data analyses were carried out using SPSS software (version 15.0). The LSD procedure was conducted to compare means of the soil properties at $P < 0.05$.

Results and Discussion

The effects of grazing on SOC and soil physical properties are shown in Table 1. The conversion of natural forest soil into soils under pasture resulted in significant reductions in the concentrations of SOC. Soil organic carbon of pasture land in the 0–15 cm, 15–30 cm and 30–45 cm soil layers was lower than in the forest plots, but the differences were not statistical significant in the 15–30 cm and 30–45 cm soil depth ($P > 0.05$). The SOC was about 3 times less under pasture compared with forest in the 0–15 cm soil layer. The lower values in pasture are probably due in differences in C inputs. In contrast to our results, in the Flooding Pampa of Argentina, cattle grazing did not affect SOC (0–10 cm depth) in an upland site, but increased it by 28% in a lowland site (Chaneton and Lavado, 1996), suggesting that topographic position modulated grazing effect on carbon cycling. Moreover, according to them, grazing effects may depend on the soil pool being sampled.
The long-term grazing had a great effect on the bulk density at all the three depths. The bulk density was 4.7–50.5% higher in pasture than in forest soil, and varied from 0.99–1.48 g cm^{-3} for forest to 1.49–1.55 g cm^{-3} for pasture, in the 0–45 cm soil layer.
Total porosity of the forest (61.0, 50.8 and 44.6% in the 0–15-, 15–30- and 30–45-cm layers, respectively) was significantly greater (4.9–36.5%) compared with pasture.
The air capacity was also significantly affected by grazing. After the conversion natural forest to pasture, air porosity decreased to 85.3%, 59.5% and 32.0% in the 0–15-, 15–30- and 30–45-cm depth, respectively. The air capacity at all three depths of pasture soil had average soil air-filled pore volume below the 10% value often cited (Rab, 2004) as the point where soil anoxia becomes a problem.
Similar to this study, Abbasi *et al*. (2007) reported that soil from grassland had 10% lower porosity than the soil from the forest at 0–15 cm depth in the hilly and mountain ecosystem in the northeast of Pakistan. In contrast, Celik (2005) reported no differences in the total porosity values between forest and pasture in the 0–10 cm layer but differed significantly in the 10–20 cm layer to ~ 7%.

Table 1. Comparison of the mean values of the studied soil properties in two studied land uses (forest – FO and pasture – PA) and depths.

Depth (cm)	Land use	SOC[†] (w%)	BD ($g\ cm^{-3}$)	TP (v%)	AP (v%)	dMWD (mm)	wMWD (mm)	FC (v%)	WP (v%)	PAW (v%)	K_f ($cm\ s^{-1}$)
0–15	FO	6.1a	0.99b	61.0a	17.5a	7.0b	2.5a	46.3a	18.7b	24.8a	$6.9 \cdot 10^{-2}$a
	PA	3.6b	1.49a	44.7b	2.6b	8.8a	2.3b	42.2b	23.6a	18.6b	$3.4 \cdot 10^{-4}$b

	PA	0.9a	1.55a	42.5b	3.2b	9.4a	1.8ab	39.3a	24.2a	15.1a	$5.5 \cdot 10^{-4}$a

[†]SOC, soil organic carbon; BD, bulk density; TP, total porosity; AP, air porosity; dMWD, dry mean weight diameter; wMWD, wet mean weight diameter; FC, field water capacity; WP, wilting point; PAW, plant available water capacity; K_f, saturated hydraulic conductivity. Numbers with the similar letters are not significantly (P < 0.05) different in two land uses in each depths.

In pasture land average dMWD values are significantly higher (8.82–9.41 mm) compared to forest (6.99–9.21 mm) at a depth of 0–45 cm which is mainly attributed to animal trampling. In the 0–15 cm soil layer, long-term pasture had 26% greater mean dMWD than forest.

As in the case of dMWD, grazing effects on wMWD. However, wMWD values in forest soil were significantly lower in pasture (1.80–2.29 mm) then in forest (2.04–2.64 mm) which is mainly attributed to the high SOC content of this soil. In forest soil at a depth of 0–15 cm, mean values of wMWD are 7% higher than in the same depth zone of pasture land. This decrease in wMWD was mostly due to a decrease in the proportion of water-stable aggregates > 3 mm. It appeared that macroaggregates of larger sizes are more sensitive to animal trampling than those of smaller sizes when a virgin soil is brought under long-term pasture.

After 20 yr of grazing, in 0–30 cm layer, the water content at field capacity was significantly lower (8.8–12.7%) in the pasture than in forest. There was no significant difference in FWC values for the 30–45 cm layer.

In 0–15 cm layer, there was an increase of 26.6% in the water content at wilting point in pasture treatment, over that of the forest soil. There was no significant difference in wilting point values for the 15–45 cm layer.

Plant available water was significantly altered by the grazing treatment in the 0–15 cm layer of the pasture land (P < 0,05), but it was not significantly altered at the 15–45 cm. Namely, results show that PAW at 0–15 cm depth significantly decreased (25.0%) due to grazing.

In contrast to our results, Sharrow (2007) found that stored soil water at field capacity tended to be numerically higher on pastures than in forests.

Differences in soil bulk density and porosity were strongly reflected in saturated hydraulic conductivity. After the conversion forest to pasture and long-term grazing, the saturated hydraulic conductivity was significantly reduced. The average value of the saturated hydraulic conductivity in the surface layer (0–15 cm) in the pasture land have decreased by 20 times, in the subsoil (15–30 cm), they became 13 times less. At a depth of 30–45 cm, the average value of the saturated hydraulic conductivity is 1.7 times higher than in the same depth zone of the forest.

Also, Singleton *et al*. (2000) found greater reductions in soil hydraulic conductivity (50–90%) under intensive cattle grazing on wet soils in New Zealand, especially on soils that were

previously damaged. Grazing compaction often results in low saturated hydraulic conductivity (Gifford and Hawkins, 1978; Willat and Pullar, 1983).
Higher soil bulk densities and a lower water content, proportion of stable aggregates, and water permeability, as a result of increased animal trampling, have been observed for different grazing animals in different grassland ecosystems (Daniel *et al*., 2002; Binkley e*t al*., 2003; Ilan *et al*., 2008). Our results were therefore consistent with previous research.

Conclusions

The degradation of the lowland soils by the grazing seriously impaired soil properties and resulted in significant increases bulk density and decreases in the soil organic carbon, aggregate stability, mean weight diameter and the hydraulic conductivity. Decreases of organic matter up to 66% and its crucial effects on soil physical properties well explained the vulnerability of the structure and function of the lowland ecosystems. In conclusion, when natural forest systems are converted for pasture without the use of proper practices of securing organic matter and soil stability, they are easily threatened. Therefore, the measures should be implemented urgently to sustain lowland ecosystems and reinstate the degraded lands in the northwest region of Serbia.

Abstract

Food insecurity concerns are as old as humanity. Food security exists when all population, at all times, has access to sufficient, safe and nutritious food. It is built on four pillars, namely food availability, food access, food utilisation, and stability. While it is widely admitted that food security increases with economic development, also rich countries in the Near East and North Africa (NENA) region, such as Qatar, face specific challenges. Therefore, this review paper analyses the state, determinants and perspectives of food security in Qatar. Since 2007-2008 global food crisis, Qatar's food security has been an ongoing challenge as the growing population is making significant pressure on the government. Based on its fiscal strength, the Qatari government adopted three important strategies: increasing local production, foreign agro-investments and long-term arrangements for food imports. As a result, in 2018, Qatar was ranked first in the Arab world and 22nd globally in the Global Food Security Index. However, denied food supplies from Saudi Arabia following the blockade in June 2017 exposed the high dependence of Qatar on imports, limits of import-based food policies and the need to increase the local production. Since then the Qatari agriculture sector has been under growing pressure to increase the local food production and to realize the highest possible level of self-sufficiency. However, agriculture is limited by several natural conditions, such as scarce water resources and poor soils, and aquifers have been heavily exploited above the average natural recharge. In addition, local food production is limited by some structural factors such as low use of modern agricultural techniques and equipment, and the poor sectoral coordination and integration within the governmental institutions. The paper makes the case for promoting a productive and sustainable agriculture, with high resources use efficiency, to increase food security in Qatar.

Keywords: *food security, food self-sufficiency, blockade of 2017, sustainable agriculture, Qatar.*

Introduction

Achieving a world without hunger and malnutrition is one of the aims of the 2030 Agenda for Sustainable Development (United Nations, 2015). In fact, ensuring access to safe, nutritious and sufficient food for all (Target 2.1) and eliminating all forms of malnutrition (Target 2.2) are prominent targets of the second Sustainable Development Goal (SDG) of the 2030 Agenda (i.e. End hunger, achieve food security and improved nutrition and promote sustainable agriculture). Moreover, the achievement of SDG2 depends on and also contributes to the attainment of many other goals of the 2030 Agenda and sustainable development as a whole (FAO et al., 2018).

Food security concept has evolved and been expanded over recent decades (Du and King, 2018; Committee on World Food Security, 2012; Gross et al., 2000; Ingram, 2011; Lang and Barling, 2012; McMichael, 2014) with a change of focus from increasing food production to improving food access. Indeed, it is increasingly recognised that attaining food security is more complicated than just producing more food, as the fundamental issue concerns access to nutritious and safe food (Dumont and Rosier, 1969; George, 1976; OECD, 2013; Prosekov and Ivanova, 2018; Sen, 1981). The 1996 World Food Summit definition of food security is still widely used (FAO, 1996). It was officially reaffirmed in the 2009 Declaration of the World Summit on Food Security (FAO, 2009a, 2009b), with the addition of social access to food: "*Food security exists when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food to meet their dietary needs and food preferences for an active and healthy life*" (FAO, 2009a). Food security is built on four pillars (Committee on World Food Security, 2012; Ericksen, 2008; FAO et al. 2013; United Nations System High Level Task Force on Global Food Security, 2011): *food availability* (i.e. sufficient quantities of food available on a consistent basis); *food access* (i.e. having sufficient resources to obtain appropriate and nutritious foods); *food use/utilisation* (i.e. appropriate food use based on knowledge of basic nutrition and care); and *stability* in food availability, access and utilization.

The most recent report on the *State of Food Security and Nutrition in the World* (FAO et al., 2018) shows that the number of undernourished people has been growing and was estimated to nearly 821 million in 2017 (17 million more than in 2016), so around one out of every nine people in the world. The situation is worsening in South America and most of Africa. Conflicts and climate change are among the key drivers behind the recent uptick in global hunger. Indeed, climate change threatens to erode and reverse gains made in ending hunger and malnutrition. Moreover, food insecurity contributes to overweight and obesity and the three burdens of malnutrition (undernutrition, overweight/obesity and micronutrient deficiencies) coexist in many countries (FAO et al., 2018).

Food insecurity and malnutrition are still relevant issues in the Near East and North Africa (NENA) region (FAO, 2015). In their discussion paper on "Food Security and Economic Development in the Middle East and North Africa", Breisinger et al. (2010) put that "…*the region's longstanding challenges persist; yet taking immediate action is more urgent in light of the recent, global food, fuel, and financial crisis and projected severe impacts of climate change*" (p. 7). While it is widely admitted that food insecurity decreases with economic development, also rich countries in the region (e.g. Gulf Cooperation Council – GCC – countries i.e. Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, and the United Arab Emirates) face specific challenges for achieving long-term, sustainable food security. Therefore, the present review paper analyses the state, determinants and perspectives of food security in Qatar not only in a changing climate but also unstable geopolitical context. Qatar is a small country located in the Persian Gulf covering an area of approximately 11,437 km^2, with a population of 2.7 million. The territory is surrounded by Gulf waters with a sole land border with Saudi Arabia. Qatar has the third largest gas reserves in the world, after Iran and Russia. Enormous hydrocarbons reserves compared with a modest national population, have made Qatar the richest country in the world with GDP per capita at USD 120,000 in purchasing power parity (PPP) terms in 2016 (Qatar National Bank (QNB), 2017).

Food security in Qatar: Limits and drawbacks of import-based food policies

Food security is an important challenge in Qatar (Box 1). Historically, food production in Qatar and in the Gulf Region was limited and based mostly on fishing, Bedouin animal husbandry, date farming and small-scale vegetable production. Since the 1970s, Qatar relies heavily on food imports to sustain its booming population. Due to its robust fiscal position, Qatar, like the other GCC countries, has been less vulnerable to price risk than other food importers (Efron et al., 2018) and able to bridge the shortfall in domestic production (Ismail, 2015a).

However, in the wake of the 2007–2008 global food crisis, food security became an ongoing challenge. Based on its fiscal strength, the Qatari government adopted three important strategies to offset fluctuations in global supply: increasing local production to realize the highest possible level of self-sufficiency through the National Food Security Programme (QNFSP), foreign agro-investments and long-term arrangements for food imports (Al-Ali Mustafa, 2017). In 2008, the government adopted the ambitious QNFSP, with the goal of increasing self-sufficiency from 10 to 70 percent by 2023. A key element of QNFSP is the deployment of advanced technologies by investing in four key areas: renewable energy, desalination and water management; agricultural production, and food processing and management (Ismail, 2015a). However, the financial and environmental costs which are expected to outweigh the cost of importing food, forced the government to abandon the plan and concentrate on foreign agro-investments and long-term arrangements for food imports (Ismail, 2015a; Al-Ali Mustafa, 2017). In 2008, the agricultural arm of Qatar's sovereign wealth fund, Hassad Food, was established in order to contribute to food security in Qatar through foreign agro-investments (McSparren et al., 2017). Since then, Hassad acquired lands in Africa and Australia, among other places (Fuchs, 2012), invest in existing agricultural business and export the produce to Qatar (Salacanin, 2013) so that it can maintain control over the food supply chain. Today, Qatar is one of the biggest regional investors (along with Saudi Arabia and the UAE) in agricultural land abroad (Al-Ali Mustafa, 2017).

Box 1. Research on food security in Qatar.

Most of the existent studies related to food security in Qatar focus merely on some aspects of food security. The first group of literature focused on the environmental aspects of food security in Qatar such as the Qatar's National Food Security Program (QNFSP) and its financial and environmental consequences (Ismail, 2015a); the water-energy-food nexus (Mohtar and Daher, 2015; Ismail, 2015b); or the sustainability of Qatar's self-sufficiency (Al-Ali Mustafa, 2017). The second group of researches focused on the geopolitical aspects of food security such as foreign agro-investment policies (Tétreault et al., 2014); or the effects of the June 2017 blockade on food supply in Qatar (Miniaoui et al., 2018).

In 2018, Qatar was ranked 1st in the Arab world and 22nd globally in the Global Food Security Index (The Economist Intelligence Unit, 2018). Notwithstanding, Qatar still imports more than 90 percent of its food and the future of food security in Qatar is challenged by two factors. Firstly, the impacts of climate change could significantly affect agriculture production through yield reductions (FAO and OECD, 2018). As a result, agricultural commodity prices are expected to remain volatile for the near future, which could result on export restrictions and speculation (World Bank, 2011). Secondly, since nearly all food imports come through the Saudi border and Hormuz Strait, the geopolitical instability of the region, threatens the security of Qatar's food supply (McSparren et al., 2017). Any disruptions to food shipments due to conflict in the Hormuz Strait would have a devastating impact on Qatar's food security (Ismail, 2015a). Furthermore, denied food supplies from Saudi Arabia following the blockade of June 2017 has exposed the high dependence of Qatar on imports.

In June 2017, Saudi Arabia, the UAE, Bahrain, and Egypt cut off diplomatic relations with Qatar and impose an air, sea, and land blockade. Prior to the blockade, Saudi Arabia and UAE accounted for 27.4 percent of Qatar's total value of food products. Meanwhile, about 80% of Qatar's food imports passed through a neighboring country, with 40% coming through the Saudi border and 60% of dairy products imported by Qatar coming from Saudi Arabia and the UAE. In response to the blockade, Qatar has adopted a range of strategies to ensure its food security. Firstly, Qatar arranged alternative trading routes and food supply chain with new partners, most notably Iran, Oman, Turkey and Pakistan (Efron et al., 2018; Miniaoui et al., 2018; Bouoiyour and Selmi, 2019). Qatar also upgraded its ports to prepare for additional shipping with the expanding of the new Hamad port. Inaugurated officially on the 5th of September 2017, the port has reached, within a short period of time, a large global connectivity coverage with 40 ports spanning over three continents (Kumar, 2018). Secondly, the blockade showed the limits of import-based food policies and the need to increase the local production in Qatar; "*One of the positive outcomes of the blockade is that it has galvanised Qatar to exploit its own agricultural production potential*" (Miniaoui et al., 2018:7).

Food production in Qatar: Limiting natural factors and structural challenges

Achieving food self-sufficiency in Qatar is not an easy task. Since Qatar is located in one of the driest regions in the world (Ismail, 2015a), the local food production is limited by several harsh natural conditions, such as scarce water resources, limited arable land and high temperatures (Abu Sukar et al., 2007). Furthermore, most of the water used in irrigation is groundwater, with a low use efficiency. Subsequently, aquifers have been heavily exploited above the average natural recharge, thus increasing water and soil salinity (FAO, 2009). Meanwhile, additional local food production requires an important increase in water and energy resources as well as intensive land use (Mohtar and Daher, 2015).

In addition, local food production is limited by some structural factors. Farming methods in Qatar are outdated and badly matched to local conditions (General Secretariat for Development Planning (GSDP), 2011). Low use of fertilizers and modern agricultural techniques and equipment, and inappropriate mixes of crops and livestock have reduced the efficiency and the productivity of the agricultural sector. Consequently, agricultural yields are generally lower than those of other Gulf States. Furthermore, laws and legislation on agricultural production do not keep pace with the country's food security strategies (GSDP, 2018). Finally, as highlighted by the Second National Development Strategy (2018-2022), the poor sectoral coordination and integration is another major institutional challenge in Qatar. This challenge reflects the lack of clarity in the overall sectoral orientation of some government sectors, such as food security and food production. Poor coordination is due to the lack of "planning culture" and "team work" that require joint action and coordination of efforts (GSDP, 2018).

Achieving food security in Qatar: Innovation in agriculture as a promising solution

Very clearly, since the blockade of 2017, the Qatari agriculture sector is under growing pressure to enhance the local food production to realize the highest possible level of self-sufficiency without depleting the natural resources. In arid and semi-arid countries, such as Qatar, where natural resources are scarce, there is a need for strategies to produce more food with less land and water. There is, hence, a need for a transition towards sustainable food systems that ensure food and nutrition security (Capone et al., 2014; El Bilali et al., 2019). In this context, new technologies and innovative practices such as hydroponics, greenhouses, modern irrigation systems (e.g. drip irrigation), and appropriate crops that would suit the local climatic conditions, can be used to increase the productivity and the sustainability of agriculture systems (Anderson et al., 2016; Sixt and Poppe, 2019); within a positive enabling environment supported by efficient policies (Hussein and El Harizi, 2013). Further, another issue related to agriculture innovation is the adoption and integration of new technologies (cf. innovations) into agricultural production. Low adoption rates of new and potentially beneficial agricultural technologies in many countries continues to contribute to food insecurity and low agricultural productivity (Ngigi, 2003). In order to identify where interventions can be targeted to optimize the functioning of the agriculture sector, it is particularly important to understand and analyze how farmers in Qatar innovate, interact to innovate, adopt new technologies and how they absorb external knowledge. In addition, it is important to analyze and understand the factors that may support or hinder technology adoption and innovation, especially water and land saving technologies. However, data about types of innovations adopted by farmers to improve food production in Qatar is scarce.

Conclusions

Since the blockade of 2017, the Qatari agriculture sector is under growing pressure to enhance the local food production to realize the highest possible level of self-sufficiency without depleting the natural resources. There is, hence, a need for a transition towards sustainable food systems that ensure food and nutrition security. In this context, new technologies and innovative practices that would suit the local climatic conditions can be used, to increase the productivity and the sustainability of agriculture systems. However, the paucity of current research on the dynamics and characteristics of innovation and technologies adoption within the agriculture sector in Qatar and its link to food security and sustainability leaves a major and worrying gap in the knowledge base needed to form effective policies. Further, studies detailing the factors that influence the interactions between the different stakeholders and what does this imply for knowledge production and exchange, and consequently innovation, are lacking. There is a need for research to identify the main obstacles and the factors that influence innovation, technologies adoption, knowledge sharing and cooperation within the agriculture sector in Qatar. Furthermore, the blockade of 2017 and the need to increase the local food production is an opportunity for a systemic and holistic approach of innovation that considers the several aspects of food production, including agricultural production, economic development, environmental sustainability, and institutions, taking into account at the same time all the elements, their interconnections and related effects. A more system-oriented understanding of how innovation occurs is critical to promoting dynamism in agriculture and, ultimately, to enhancing agri-food productivity and sustainability in Qatar.

GEOGRAPHICAL ORIGIN OF INVASIVE PLANT SPECIES IN THE WORLD AND SERBIA

Abstract

Invasive species are regarded as one of the biggest biodiversity threat on the planet. Globaly considered and having in mind the organisms of all the taxonomical categories, the highest number of invasive species is of Euro Asian and South American origin. However, analyzing the content of invasive flora in different regions, different species presentation, due to specific geographical origin, can be noticed because of the climate characteristics of each region. Although plant species of Old World are regarded competitively superior in relation to plant species of the New World, percentage predominance of European species is recorded only in the parts of the world with similar climate characteristics, such as the parts of North America. Among invasive plant species in Serbia, the most dominant are those of North American (approx. 67%) and Asian origin (approx. 24%). South American origin has been found in about 9% invasive plant species, European in about 6%, African in about 4%, while 3% of invasive species are hybrids. Those species with native distribution in more than one continent are assigned to each of the continents. Although North American species, on the global level, do not definitely belong to species groups with the biggest invasive potential, they are predominant according to their presentation among invasive species in Serbia. It can be explained by climate similarity of the parts of North America and Serbia, phylogenetic distance of North American and Serbian flora and economic-trade connections of Europe (therefore Serbia, too) with North America.

Keywords: *Invasive plant species*, *Geographical origin*, *Serbia*.

Introduction

Since invasive species present bigger and bigger problem worldwide, it is very important to know the basic characteristic patterns of their distribution. There is an accepted opinion that the Old World plants, especially European, have higher invasive potential than the others, making them dominant among alochton flora of other regions. According to Rapaport (2000), practically all European species introduced in other parts of the world have bigger chances to become adventive in comparison to the species that originate from other regions. Di Castri, in his book from 1989, marked European plants as "highly invasive". However, some of the mentioned examples point out that hypothesis of invasive superiority of European plants can't be applied universaly.

According to Lambdon *et al*. (2008), the highest number of naturalized European species have European origin, i.e. even 53,2% of the total registered naturalized species in Europe are native for some other part of Europe. According to Khuroo *et al*., (2012) more than one third (35%) alochton flora of India are species that originate from Latin America, most of them from Mexico and Brasil. However, when only invasive species are considered (as subset of alochton species), even more than a half (52%) originate from Latin America. Among naturalized and invasive species of China, the most are of American origin (Weber *et al*. 2008; Huang *et al*, 2009; Wu *et al*., 2010), i.e. as in India the most invasive plants originate from the tropic parts of Central and South America. Most plants that are invasive in Brasil have European origin (Zenni, 2014). However, if we regard Europe as donor region separated from Asia, it can be noticed that European species are presented in a small number of species

compared to the species from other continents. According to Castro *et al*. (2005), 323 alien species in Chile have EuroAsian origin, 63 American, 42 species originate from the other parts of the world. The biggest role in flora homogenization of North and South America have the species of European and Asian origin. In North America the most widely distributed species originate from some other continent: approx. 85% have European origin, 7% EuroAsian, 3% Asian (Stohlegren *et al*., 2011).
Geographical analysis of Australian invasive species was the subject of Philips *et al*. (2010), but with a little bit different approach: they examined percentage part of invasive species in the total number of alochtonic species presented in Australia, for each donor region separately. Beside this, they took into consideration residence time that passed from introduction of each species in Australia. This method can lead to more correct conclusions about species invasion (sensu stricto) in some regions in contrast to comparison of the presented invasive species number. It is interesting that Australia has more invasive species from South America than it is expected, and less from Europe and Australia.
The aim of this paper is to determine the regions in the world from which the largest number of invasive species come to Serbia, to show the content of invasive flora in Serbia according to geographical origin as well as to compare the presentation of invasive species of different geographical origin in Serbia to world class data.

Material and Methods

Preliminary list of invasive species in Serbia according to Lazarević *et al*. (2012) was used for the purpose of this paper. The authors of it noted 67 taxons as invasive plants in Serbia dividing them into three groups: highly invasive, sporadically invasive and potentially invasive. The data of these species origin are taken from the site Centre for Agriculture and Bioscience International Invasive Species Compendium (CABI ISC, 2018) and Invasive Alien Species in Vojvodina (IASV, 2018).

Results and Discussion

Analysis results of the geographical origin of invasive plant species in Serbia mostly depend on the choice of the list that is used. In other words, different sources note different species as invasive making the term "invasive" not used universally. Foreign sites dealing with this subject are not usable in this case since they don't have complete data when Serbia is in question. So, for example the site Global Invasive Species Database (GISD) for Serbia notes only three invasive species: *Impatiens glandulifera*, *Luzula campestris* and *Salsola tragus*[8], while Delivering Alien Invasive Species Inventories for Europe (DAISIE) list of invasive plant species does not exist in Serbia. According to Turbelin *et al*. (2017) there are 18 types of all taxon category organisms in Serbia making that number not real having in mind that only Pannonian part of Serbia has even 152 species of alien invasive neophytes (Anačkov *et al*., 2013).
The list of invasive taxons (according to Lazarević *et al*., 2012) with their geographical origin (according to CABI ISC, 2018 and IASV, 2018) is given in Table 1.

[8] Neither domestic author state *Luzula campestris* as invasive, but according to the site Euro + Med Plant Base, it is regarded as native in Serbia. According to the same site, *Salsola tragus* is not noted for Serbia, but is native for some surrounding countries.

Table 1. Invasive plant taxons in Serbia (according to Lazarević *et al.*, 2012) and their geographical origin (according to the data from the site CABI ISC 2018 and IASV 2018)

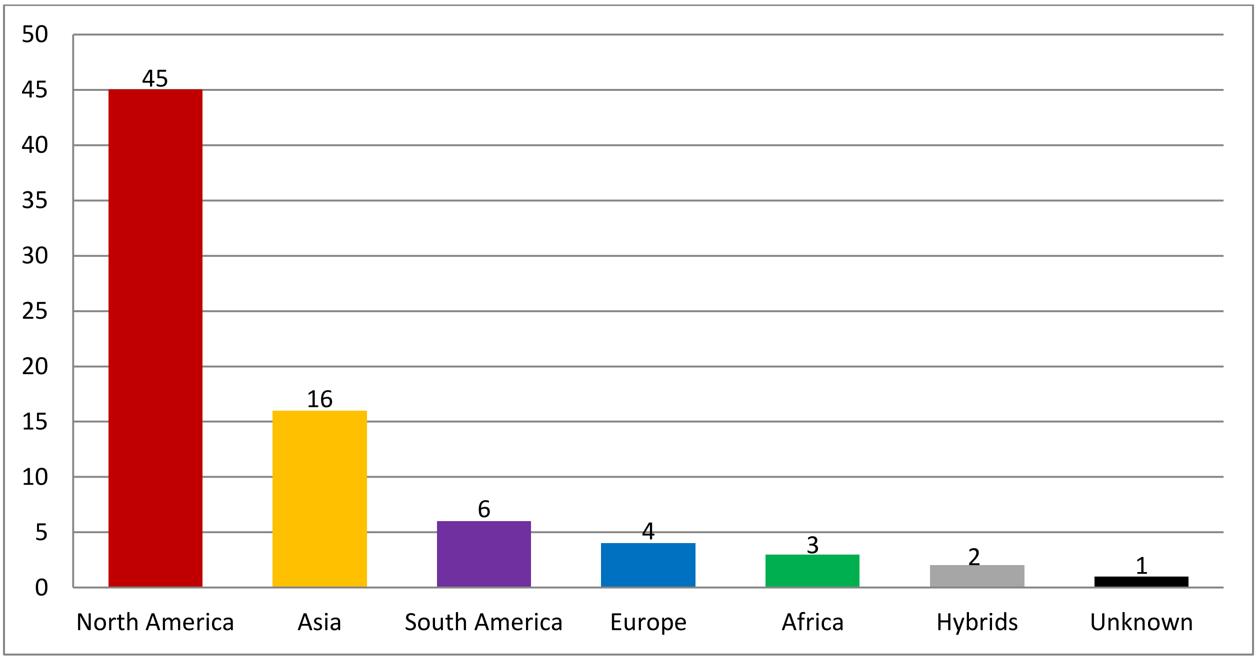
Among invasive plant species in Serbia the most numerous are those of North America origin, i.e. native range for even 45 to 67 taxons is North America (approx. 67%), while 4 among them are native both for North and South America. The second place belongs to taxons where Asia is their native range (16), but some of them are regarded as native both for Europe and Asia. South America is considered as native range for 6 taxons, while those that are "unique" for South America (alochton for North America) are only 2. Among alien species that are invasive in Serbia are 4 species that are native for some other part of Europe. Mostly these species, beside Europe, are regarded native for Asia, or both for Asia and Africa. For entirely three species native range is Africa, while only 1 has African origin exclusively, i.e. is regarded alochton in Europe and Asia. Two species are hybrids, while for one, primary areal has not been definitely determined yet (Graphic 1).



Graphic 1. Geographical origin of invasive plants in Serbia (those with native distribution in more than one continent were assigned to each of the continents)

North American species on the global level definitely do not belong to the group of species with the highest invasive potential, i.e. the largest number of invasive species originate from South America and EuroAsia. However, North American invasive plants are predominant in Serbia, which means that Serbia does not suit to global pattern. The reason for this can be found in climate similarity between Serbia and some regions in North America (Fig. 1).

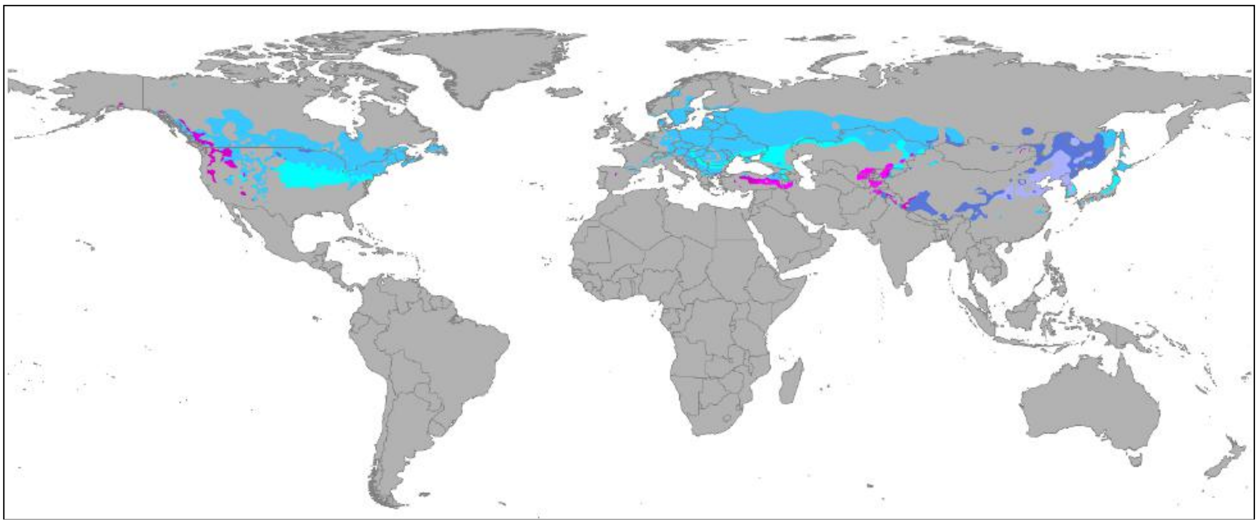


Fig. 1 The map that presents regions with different varieties of moderate continental climate in the world, according to Koppen-Geiger climate classification (according to Peel *et al*., 2007)

Although the regions with similar type of climate exist in Asia, they are not enough far from the territory of Serbia, so they have a large number of the same native species. Also, North American flora is for sure phylogenetically less related to the flora in Serbia, compared to flora of some parts in Asia with similar climate, and according to Strauss (2006) "exotic taxa that are less related to native ones are more invasive than the others". Beside all these, high level of alien species introduction from North America into Europe (being the consequence of these two continent economic-trade connections), directly or indirectly into Serbia too, is very important fact so when we take it into consideration, it is clearly obvious why North American species are so numerous and considered invasive in Serbia.

Climatic mis-match can be considered as the basic reason why South American species are less presented in Serbia in spite of phylogenetic distance of these flora, meaning that climate is the key factor on which geographical origin of invasive plants in Serbia depends. African species are obviously less presented than South American because besides climatic mis-matching there is a fact that African and European flora is phylogenetically closer to each other.

Conclusions

In Serbia invasive species that are mostly presented are those from North America continent and the reasons for that are as follow:

- Climate similarity of North America and Serbia parts;
- Phylogenetic distance of North America and Serbia flora;
- Economic-trade connections of Europe (therefore Serbia too) with North America.

Biogeographical patterns of invasive species distribution are very complex and under the influence of many factors. What is important on global level, need not be important on regional when climate characteristics of each regions are of great importance. It is not possible to mark some species as those with universaly high invasiveness, for what is invasive for one climate, need not be invasive in the other. So, when we talk about the invasion of some plant (or group of plants) it is necessary to have in mind geographical, i.e. climate characteristics related to that invasion. Also, the attention must be paid on the fact that each case of invasion is unique and depends on species characteristics, as well as the environmental ones. All this indicates the importance of risk assessment during plant species introduction in new regions and dangers of making wrong decisions if made on stereotype conclusions. Because of this, as well as the fact how invasive species are dangerous for biodiversity, examinations of all the aspects of invasive species (biogeographical too) will be of great importance in future.

Abstract

Due to the scarcity of water and for efficient use, many reservoirs, hillside dams and hillside lakes have been built mobilizing more than 90% of surface waters. These man made environment have biological potential that deserves to be better well known, monitored, exploited and managed. This review attempts to collect information on some dam reservoirs biodiversity in Tunisia from bibliographic studies for sustainable management. Investigations conducted in some Tunisian reservoirs revealed the presence of 185 phytoplanktonic species. Cyanobacteria branch was the most diversified with 52 species, some of which are potentially toxic and can be considered as a nuisance for water usages like drinking water, irrigation, fish farming or recreation. The Autochtonous tunisian freshwater fish biodiversity is low and limited to five families: Anguillidae, Cyprinidae Cyprinidontidae, Gobidae and Pœciliidae. Autochthonous marine fish species (Mullets) as well as freshwater fish species native from Eastern Europe and Western Asia have been introduced in few reservoirs for the diversification of livestock and the promotion of inland fishing. The avifauna of reservoirs in Tunisia is quite diversified. Some have a special status and are considered vulnerable to endangered species. Most of the reservoirs in Tunisia are poor in both submerged and emerged macrophytes which may affect diversity and abundance of water birds. The environmental and ecological conditions in these reservoirs seem to favor the growth of species belonging to different biological compartments but resource management is not sufficiently efficient.

Keywords: *Reservoirs, Biodiversity, Management, Tunisia.*

Introduction

Tunisia is one of the countries particularly vulnerable to climate change, which will intensify the variability and aridity that now affect the largest part of the country. The average rainfall over the entire territory is only 230 mm / year but the extreme annual averages vary from more than 1500 mm in the northwest of the country to less than 50 mm in the southwest (Henia and Benzarti, 2005). The characteristics of the water resource (scarcity, irregularity) in addition to population growth and especially the urban population and the evolution of the economic sectors that consume large amounts of water and the country's low adaptability are all factors that contribute to the fragility of this resource in the face of climate change and basic management that needs to be reconsidered. In this context, many dams have been built last decades in Tunisia mainly in the wettest area, particularly in the north and centre of the country mobilizing more than 90% of surface waters (ITES, 2014). Based on water quality, these reservoirs were used for many purposes: consumption, irrigation, fish farming, groundwater recharge, downstream infrastructure protection and energy production, allowing rural populations to settle and benefit from employment opportunities.
In Tunisian inland waters, inventories of fauna and flora species and trophic networks linking species to each other and their environment are still poorly documented, thus hindering the

management of ecosystems as a whole. Thereby, several studies on the eco-biology and exploitation of freshwater fish have been undertaken in particular for commercially valuable fish (Djemali et al., 2009; Hajlaoui et al., 2016; Mili et al., 2016; Laouar and Djemali, 2018) however, only a few studies have focused on the other communities such as macrophytes, invertebrates and avifauna thus limiting the further exploitation of data. This review attempts to gather information on some dam reservoirs biodiversity in Tunisia from bibliographic studies for sustainable management that would be compatible with water availability and quality.

Material and Methods

This study is based on bibliographic data on the biological potential of dam reservoirs in Tunisia located in different watersheds in an attempt to improve their management. These data, collected over the period 1983-2019, yielded useful information on various fauna and flora communities.

Results and discussion

Water surface management

Tunisia, a semi-arid country, remains very vulnerable to water resources where the exploitable volumes of surface water mobilized are about 2500Mm3/year**.** Water potential is highly dependent on rainfall which is rare and irregular. In addition to extended periods of drought, most wet precipitation occurs during short periods of heavy rainfall, which causes strong runoff with excessive erosion of soils, part of which will be carried to dam reservoirs (Saadaoui, 1995). Silting of reservoirs is causing a reduction in their storage capacity that remains a major problem despite the redevelopment and maintenance works (Abid, 2003; Ben Mammou and Louati, 2007). Thus, for improved management of water storage in reservoirs, it is necessary (i) to limit runoff through cultural practices and vegetation cover. However, a collective reflection must be carried out and implemented at the scale of the catchment area. (ii)to consider the surpluses of rainy years, which are not yet under control, to minimize losses and ensure better water mobilization and consequently better availability and exploitation.

Phytoplankton communities

In aquatic ecosystems, phytoplankton is the first link in the food chain. Its development conditions that of the primary consumers which regulate in turn the development of secondary consumers. Thus, because of its position in aquatic food webs and its high sensitivity to changes in environmental conditions, phytoplankton is a real tool designed for decision support and management of evolving water bodies. Several studies have shown that phytoplankton from Tunisian inland waters is highly diversified where more than 187 taxa belonging to 7 classes have been identified (Ben Rejeb Jenhani et al., 2019). Cyanobacteria branch was the most diversified with 52 species, some of which are potentially toxic and can be considered as a nuisance for water usages like drinking water, irrigation, fish farming or recreation with many health, ecological and economic consequences (figure 1). Cyanobacterial blooms have been observed in summer-autumn period following the proliferation of one or a few species under favorable hydroclimatic conditions (stability of the water column, high temperature, drought) and in particular nutrient enrichment from watersheds (Ben Rejeb Jenhani et al., 2006; El Herry et al., 2008; Fathalli et al. 2010; Fathalli et al.2015). Thus, to preserve water quality for multiple uses, it is necessary, through coherent management actions, to adopt a strategy to prevent eutrophication by upstream monitoring of nutrients, by managing water flows through regular desilting and cleaning actions and by screening toxic species through spatial and temporal monitoring. The strengthening of fundamental scientific knowledge on phytoplankton communities will make it possible to better elucidate the determinism of the appearance of toxic blooms.

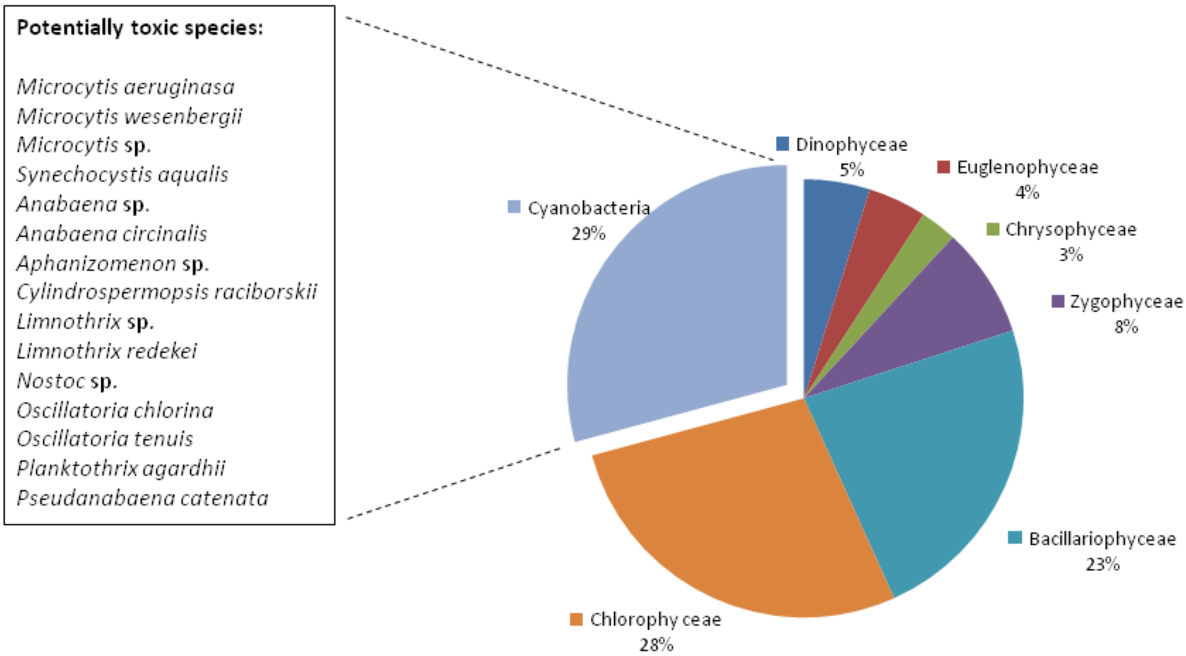

Figure 1: Rate of phytoplankton classes and potentially toxic cyanobacteria identified in Tunisian reservoirs

Fish communities

Tunisian fresh waters are poor in fish (Kraim, 1983). Several attempts have been made to introduce in reservoirs various species of Asian, European and African origin in order to diversify the livestock population, as forage or commercial fish. Indigenous and introduced fish stocks belong mainly to 8 families: Mugilidae, Percidae, Pœciliidae, Siluridae, Cyprinidae, Cyprinodontidae, Gobidae and Anguilladae**, (**table 1). Only about thirty of the more than forty dams are affected by fishing activity, which is based on an active fleet of 250 non-motorized boats and a population of about 500 fishermen (DGPA, 2016). The total production in these reservoirs over the last decade is between 870 and 1350 t/year. This production comes mainly from the Sidi Salem (51.5%), Sidi Saad (19.5%) and Sidi Barrak (7.5%) reservoirs. The distribution of production by species shows the predominance of mullet (34%), carp (28%) and pike-perch (17%,) (DGPA 2016, Laouar, 2019). This production is related to the stocking efforts of mullet fry and the transfer of spawners, which have sometimes been found to be deficient, causing a decrease or stagnation in production, in addition to illegal fishing activity that has not yet been controlled (Hajlaoui et al., 2017). Moreover, the fisheries statistics that are the foundation of any long-term planning strategy remain unreliable.

Table 1. Autochtonous and introduced fish in Tunisian reservoirs

Family	**Species**	**Status**	**Diet**
Anguilladae	*Anguilla anguilla*	Autochtonous	Omnivorous
Mugilidae	*Mugil cephalus*	Autochtonous	Omnivorous
	Liza ramada	Autochtonous	Omnivorous
Percidae	*Sander lucioperca*	Introduced	Carnivorous
Siluridae	*Silurus glanis*	Introduced	Carnivorous
	Barbus callensis	Autochtonous	Omnivorous
Cyprinidae	*Cyprinus carpio*	Introduced	Omnivorous

	Scardinius erythrophthalmus	Introduced	Omnivorous
	Rutilus rubilio	Introduced	Omnivorous
	Pseudophoxinus chaignon	Autochtonous	Omnivorous
Pœciliidae	*Gambusia offinis*	Introduced	Insect larvae and small invertebrates
Cyprinodontidae	*Aphanius fasciatus*	Autochtonous	Omnivorous
Gobidae	*Pomatoschistus marmoratus*	Autochtonous	Omnivorous

Water Birds communities

Furthermore, dams, by creating artificial water reservoirs, are rather beneficial for birds, especially migrants who find new or compensatory resting and breeding areas. The avifauna of reservoirs in Tunisia is quite diversified and is spread over several families. Nine of reservoirs in Tunisia are, due especially to their ornithological richness, included in the Tunisian list of the international Ramsar agreement (www.ramsar.org) and five as Important Bird Area (www.birdlife.org). Lebna reservoir is the most visited with more than thirty species represented by several tens of thousands of individuals (FDR 2007). Some have a special status and are considered vulnerable to endangered species: *Platalea leucorodia*, *Marmaronetta angustirostris*, *Aythya nyroca* et *Oxyura leucocephala* (table2). The last two species, recorded in Lebna, exceeded the 1% threshold of their biogeographic population in Tunisia during the 2009 census (Feltrup-Azafzaf and Azafzaf, 2009). Birds censuses are generally variable according to years and are largely dependent on climatic, anthropogenic and environmental hazards. Most of the reservoirs in Tunisia are poor in both submerged and emerged macrophytes which are represented by reed stands (Thyphaceae, Poaceae) on the banks and farther, in the deeper zone, we find *Potamogeton* (Potamogetonaceae) and *Myriophyllum* (Haloragaceae). Filamentous algae such as *Chaetomorpha* (Cladophoraceae) are also reported (Loss et al. 1991). Riparian and aquatic vegetation, which is essential for water-birds, is often subject to variations in water levels due to different uses (irrigation, hydroelectric production, drinking water requirements) and to drought thus disrupting the presence of birds, adds illegal hunting, poaching, stocking and eutrophication. Despite annual bird censuses, management plans remain deficient in Tunisia. National plans, in collaboration with international species conservation actions, should be implemented for the protection of threatened species and habitats.

Table 2: Avifauna inventory in Tunisian reservoirs

Order	Family	Specific diversity	Species status (UICN, 2012)
Gaviiformes	Gaviidae	1	
Podicipediformes	Podicipedidae	3	
Procellariiformes	Diomedeidae	1	
Suliformes	Phalacrocoracidae	1	
Ciconiiformes	Ardeidae, Ciconiidae	6	
Pelecaniformes	Threskiornithidae	2	*Platalea leucorodia* (NT)
Phoenicopteriforme	Phoenicopteridae	1	
Anseriformes	Anatidae	16	*Marmaronetta angustirostris* (VU) *Aythya nyroca (EN)* *Oxyura leucocephala (EN)*
Gruiformes	Rallidae, Gruidae	5	

Charadriiformes	Haematopodidae, Recurvirostridae, Burhinidae, Charadriidae, Scolopacidae, Laridae, Phalaropodinae, Sternidae	43	
Coraciiformes	Alcedinidae	1	

(NT): Near Threatened; (VU): Vulnerable; (EN): Endangered

Conclusion

Tunisia is a semi-arid country with a very high vulnerability to climatic changes leading to a high environmental vulnerability of aquatic ecosystems especially in periods of prolonged drought or heavy floods. These unpredictable phenomena favour the siltation of reservoirs and the installation of favorable conditions for harmful algal blooms reaching different levels of aquatic food webs. For the preservation of available water resources, an improvement in water storage conditions is required (desilting during floods, optimization of cultural practices, reforestation, watershed management, protection perimeters). In addition, the development of tools for forecasting and managing the response of aquatic ecosystems to climate variability (monitoring indicators, mathematical models, etc.) will preserve biodiversity, habitats and environment.

Abstract

Genus *Adonis* comprises 32 species distributed in Europe and Asia. *Adonis vernalis* commonly called Pheasant's eye is a valuable medicinal plant characterized by high content of cardiac glycosides. Due to its toxicity, nowadays it is not among the most popular medicinal plants but is used frequently as homoeopathic remedy. *A. vernalis* grows on open limestone habitats with steppe character. Its distribution in Bulgaria is scattered in the northern and western parts of the country. It is an important part of the natural habitats of European importance included in the network Natura 2000: 40A0 Subcontinental Peri-Pannonic Scrub and 6210 Semi-natural dry grasslands (Festuco-Brometalia). Resource assessment was performed in natural localities situated in three floristic regions: Sredna gora, Znepole region and Sofia region. Floristic composition is rich and is typical for the calcareous sites. The predominant species are *Dichanthium ischaemum, Satureja montana, Amygdalus nana, Rosa spinosissima, Veronica austriaca, Syringa vulgaris, Pulsatilla montana, Inula oculus-christi*, but also some rare and endemic species occur: *Anacamptis pyramidalis, Ophrys cornuta, Gymnadenia conopsea, Anthylis aurea, Edraianthus serbicus*. The projective cover of *A. vernalis* is 15 – 20% and the population status of the species is stable. The resources were assessed and the estimated yield was 18 g/m^2. Continuous monitoring on the population status will provide valuable information for its sustainable use and conservation.

Key words: *sustainable use, medicinal plants, conservation*

Introduction

Conservation and sustainable use of the natural plant resources is a complex task, requiring coordination of numerous efforts and activities. This issue encompasses broad range of studies and inventories of the available plant resources, evaluation of their population status, possible threats and finally – development of strategies and plans for conservation and management for particular plant species in particular regions (Heywood & Iriondo, 2003). Monitoring and inventory of the natural resources are an integral part of each conservation and management plans. The issue is of particular importance also for the resources of medicinal and aromatic plants (MAPs), which are subjected to exploitation (Carvalho and Frazão-Moreira, 2011).

Bulgaria is among the richest countries in medicinal plant resources in Europe (Evstatieva et al., 2007). Almost ¼ of the natural plant species occurring in the country are being used, or can be used, as MAPs. There are 745 species listed in the annexes of the Medicinal Plant Act of Bulgaria (Anonymous, 2000) and this number reflects the great plant diversity in the country, which is due at least to the very diverse environmental conditions, resulting in a great diversity of habitats. And because different habitats are expected to be influenced differently by the environmental, including climate changes, the monitoring on plant resources should focus primarily to the most sensitive and threatened plant species and habitats. One of the species selected for monitoring and inventory of its natural resources in Bulgaria is *Adonis vernalis* L. (Figure 1).

Depending on the taxonomic concept applied, genus *Adonis* contains between 20 and 30 (32) species, distributed in Europe and Asia (Tutin 1964; Shang et al., 2019). There are about 10 species naturally occurring in Europe (Euro+Med Plantbase, 2019) and six species – in Bulgaria (Panov & Assenov, 1970). Some of the species are characterized by high content of cardiac glycosides and are used in the folk medicine (Shan et al., 2019). Of perennial species, *A. vernalis* is the most popular one in Europe, even though nowadays it is not among the most popular medicinal plants, due to its toxicity. It is used, however, as a homoeopathic remedy.

Figure 1: *Adonis vernalis* in its natural locality

A. vernalis grows on open limestone habitats with steppe character. Its distribution in Bulgaria is scattered in the northern and western parts of the country (Panov & Assenov, 1970). Even though it is not subjected to exploitation, its populations could be threatened by the human pressure – construction works, livestock breeding and other agricultural activities.

In the light of the above statement the objective of the present study was to perform an inventory of representative localities of the species in Bulgaria. The information could be of use for the need of monitoring of species' resources and the effect of environmental changes.

Material and methods

Three natural localities were included in the pilot study. They were selected to represent typical populations of the target species (*Adonis vernalis*) and also, to reflect the available diversity of site conditions. Two of the experimental plots are in the region of Sofia, and one – in the region of Pernik in Bulgaria. The field studies were performed in April and May, 2019. The geographic coordinates of experimental plots are:

1. Lozenska Mts – near the village Lozen, 42°35' 52" N; 23°29' 12" E, altitude 760 m a.s.l. (called hereafter L-site)
2. Golo Bardo – near the village Studena, 42°31'27" N; 23°05'49" E, altitude 1000 m a.s.l. (called hereafter G-site)
3. Beledie Khan – near the village of the same name, 42°54'44"N; 23°09'54"E, altitude 900 m a.s.l. (called hereafter B-site).

Experimental plots (50 x 20 m) were set in the estimated central part of the populations of *Adonis vernalis*. In each plot, number of individuals of the target species were scored, and plant species composition was inventoried. The projective cover was estimated based on smaller experimental plots (1 x 2 m). The species composition was based on one visit to the experimental plots – in April, during the flowering period of the target species. Some species were added based on other visits to the sites. Doubtless, the species composition could be (and will be) updated during the next inventories of the experimental plots. In the present paper we report only the results of the first-year observation.

The phytogeographic affiliation of the species followed these of Walter (1985) with slight modifications.

Resource evaluation was performed following Shrëter & al. (1986), with slight modifications.

Results and discussion

Total of 84 species were identified in the three experimental plots (Table 1). This species diversity can hardly be evaluated as high, given the peculiarities of the sites where the populations grow, but as stated above, the inventories were done mostly in the spring, when *A. vernalis* occurs and represent mostly the spring aspect of the flora. It is expected that the floristic inventory and analysis will be enlarged and deepened. Twenty-eight species were recorded in the locality in Lozenska Mts (L), 45 species in Golo Bardo (G) and 57 species in Beledie Khan (B) localities. There were 18 trees and shrubs, including small shrubs like *Satureja montana* and *Hyssopus officinalis*. However, the tree species were represented by single individuals and small groups scattered across the area and did not represent forest community, where *A. vernalis* could not have occurred.

Table 1. List of the species recorded in the three study sites.

Species	Study sites		
	Lozenska Mts (L)	Golo Bardo (G)	Beledie khan (B)

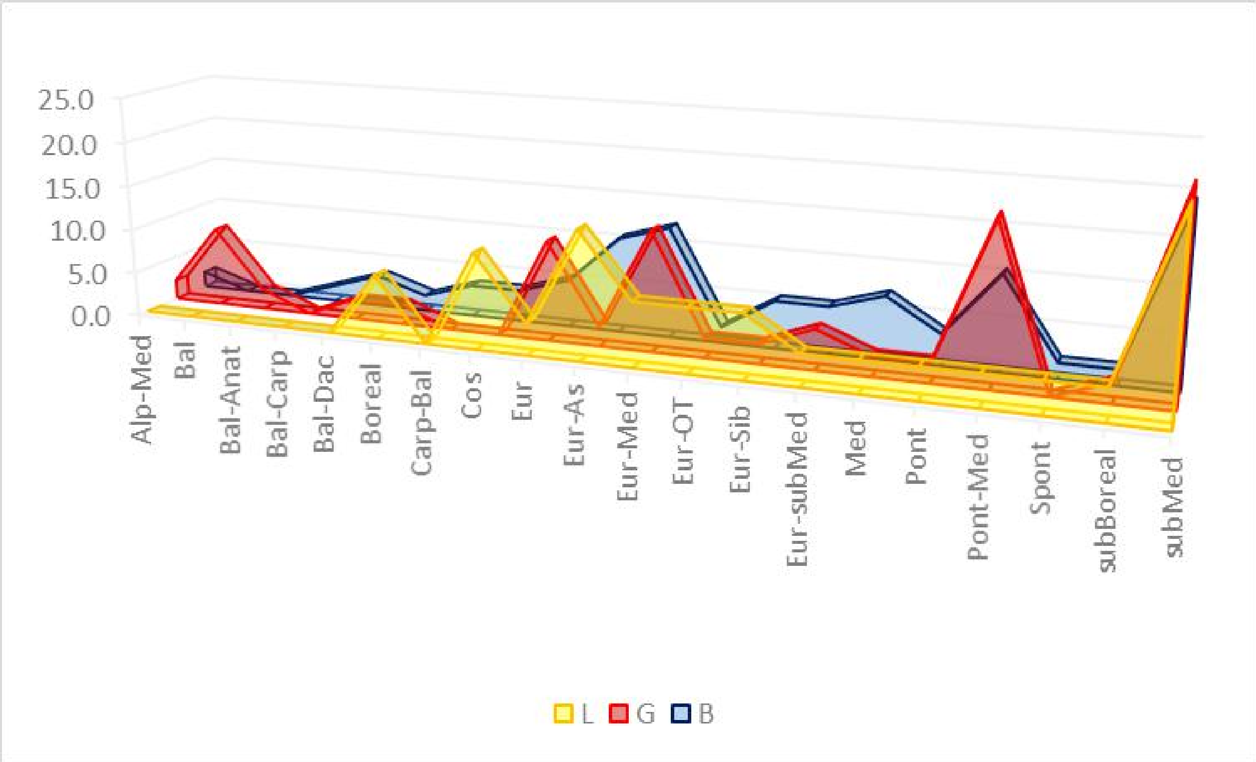
Besides the fact that locality in Lozenska Mts is poorest in species composition, it seems most affected by the human pressure, which is easily explained by the close proximity of the village of Lozen and a bit further – of Sofia. The human pressure is reflected in the species composition, including some cosmopolitan and ruderal species, like *Cynodon dactylon*, *Poa pratensis Cirsium ligulare* (Table 1). The other two localities are richer in rare species, including few endemics and sub-endemics, among them *Achillea ageratifolia*, *A. serbica*, *Anthyllis aurea*, *Edraianthus serbicus*, *Tragopogon balcanicum*. Sørensen-Dice affinity coefficients were lower (0.38 and 042) between L, and G and B, respectively, while between G and B it was 0.55. This could be explained again by the anthropogenic influence on the L site.

The phytogeographic analysis (Figure 2) showed that the most common were the submediterranean phytogeographic elements - they predominated in all experimental plots. Second position in the sites G and B was occupied by the Pontic-Mediterranean elements, but not in the site L, where the Euro-Asiatic elements were also well represented.

Generally, the species with Mediterranean component (Med, subMed, Eur-Med etc.) were the most represented phytogeographic elements – 39 % in L, 62 % in G, and 56 % in B, respectively. Elements with Pontic component were the second most numerous and constituted 11 %, 22 %, and 15 % in the experimental plots L, G, and B, respectively. These patterns of phytogeographic origin fit completely to the peculiarities of the plant communities (Velchev, 1962).

Figure 2. Phytogeographic origin of the species recorded in the three study sites. L – Lozenska Mts, G – Golo Bardo, B – Beledie khan



The projective plant cover in the three localities varies from 70 to 90 %, and that of *A. vernalis* in all localities ranges roughly from 15 to 20 %.

The natural habitat where the experimental plots were set is 40A0 Subcontinental peri-Pannonic scrub (Gussev, 2009; Tzonev & Gussev, 2015). Moreover, *A. vernalis* is one of the species characterizing the habitat type. At least half of the characteristic species listed by Tzonev & Gussev (2015) was recorded during the field survey.

A. vernalis occurs in Bulgaria as a part of some other habitats, too; however, in one of them it has more visible and substantial presence: 6210 Semi-natural dry grasslands and scrubland facies on calcareous substrates (*Festuco-Brometalia*). No experimental plots were set in this habitat, but it was registered during the process of preliminary inventory of the species locality in Bulgaria (Tzonev, 2009). *A. vernalis* was found also in some other habitats, exclusively on calcareous soils, but with sporadic occurrence, and therefore, of little interest for monitoring and resource investigations.

The resource assessment revealed that the highest stock – 25 g/m^2 – was recorded in the site B, while in the other two sites the results were practically the same – 14 and 15 g/m^2 in the sites L and G, respectively.

Conclusion

The results of the study provide information, which could be useful in relation to future monitoring and assessment. It will allow following the trend of development of populations and habitats and will provide important insight regarding their conservation, management and sustainable use.

Acknowledgment

The authors express their thanks for the support provided by the Bulgarian Ministry of Education and Science under the National Research Programme "Protection of environment and reducing the risk of hazards and natural disasters" approved by DO № 230/06.12.2018.

CLIMATE CHANGE ADAPTATION OPTIONS IN LATVIA'S AGRICULTURE

Ligita MELECE*, Ilze SHENA

Institute of Agricultural Resources and Economics, Latvia
*Corresponding author: ligita.melece@arei.lv

Abstract

Environmental impacts of agriculture under a changing climate are considered more and more important. To avoid or at least reduce the negative effects and exploit possible positive effects of climate change, adaptation strategies and measures should be developed and implemented. Adapting agriculture to climate change has linkages with other policy areas, including water management, economic policies, climate change mitigation policies, as well as infrastructure, health, and other sectors and policies that foster sustainable development and increase resilience of communities as a whole. There are various widely accepted and evidence based effective climate change adaptation options proposed by scholars and experts for agriculture sector. Most important of them, for example, are the following: agricultural input efficiency; improving (i.e., less energy-intensive) farming; reducing N surplus and N use efficiency via fertilizer usage; crop and soil management strategies' change, such as tillage practices, permanent crops; crop rotations and use of cover crops or catch crops, organic farming, green manuring; as well as reducing and/or completely removing agrochemicals; carbon sequestration and improve soil physical, chemical and biological properties. Furthermore, implementation of agro-ecological and conservation agriculture principles that affect biodiversity conservation (agrobiodiversity; i.e., crop genetic diversity) and supports many ecosystem services. Adaptation measures include technological advancements, adaptive farming practices, etc. The paper presents results of current situation's evaluation, analysing above-mentioned measures implementation status, as well as provides proposals for implementation of most promising adaptation measures in Latvia's agriculture. Moreover, necessary policy decisions and public financial support (i.e., RDP 2014-2020, RDP post 2020) are indicated.

Keywords: adaptation, climate change, agriculture, Latvia.

Introduction

The impacts of climate change become increasingly evident for the agricultural sector, as well as rural areas in general (Olesen et al., 2011; Shelton et al., 2018). From other side recent (intensive) agriculture is an important contributor to climate change. To avoid or at least reduce the negative effects of climate change, adaptation strategies and measures should be developed and implemented. Both mitigation and adaptation are aimed to reduce undesirable consequences; and can jointly contribute to the climate change strategies. There is a growing argument that synergistic approaches to adaptation and mitigation could bring substantial benefits at multiple scales in the land use sector (Duguma et al., 2014), which rises a growing interest by scholars and practitioners of agriculture and landscape management for it (Locatelli et al., 2015).

Lal et al. (2011) stress that being a source and a cause of the problem, agricultural ecosystems can be a sink of atmospheric CO_2 and reduce GHG through the adoption of sustainable land management options. An ecosystem-based approaches are recognised as most promising, which address the crucial links between climate change, biodiversity and sustainable resource management; and, by preserving and enhancing ecosystems, enable society to better mitigate and adapt to climate change. Besides, some mitigation/ adaptation options, which are typically best management practices already, raise resilience of farms, and lower farm emissions,

simultaneously also contributing to cost savings and thus increasing farm profitability (Frelih-Larsen & Dooley, 2015).
The aim of presented study was twofold: 1) to evaluate current situation, analysing implementation of mitigation/ adaptation measures to climate change; 2) to propose of most promising adaptation measures for Latvia's agriculture and landscape.

Material and Methods

The principal materials used in the studies are as follows: various sources of literature, e.g., scholars' articles, the reports of institutions (esp. EU), etc. The data were obtained from Eurostat database (http://ec.europa.eu/eurostat/data/database) and database of Central Statistical Bureau – CSB (http://www.csb.gov.lv/en/dati/).
Despite the Baltic Sea region countries are also non-EU countries, only EU member states—Denmark, Estonia, Finland, Germany, Latvia, Lithuania, Poland, and Sweden—are included for state and trends' evaluation; and are indicated as the Baltic Sea countries.
The mixed methods, combining suitable qualitative (monographic; analysis and synthesis, etc.) and quantitative (correlation-regression analysis) research methods have been used.

Results and Discussion

Intensification of agricultural production has caused several undesirable consequences: an increase of monocultures, application of agrochemicals (i.e. pesticides, mineral fertilizers); reduction the biodiversity (i.e., agricultural, wild and soil) (Tsiafouli et al., 2015; Melece & Shena, 2018). These processes contribute to further climate change.
Nitrogen management – is aimed to reduce and optimise usage of N fertiliser. Indicator—gross nitrogen balance (GNB)—balance between N added to agricultural land and that removed from it. GNB provides: an indication of the potential surplus of N; trends of N inputs and outputs; and characteristics of soil N resources (EEA, 2018; Eurostat, 2018).
Between 2000-2003 and 2012-2015, the GNB in most of the EU countries, as well as the Baltic Sea countries showed a decrease. Conversely, two of the Baltic Sea countries – Latvia and Poland show an increase (Fig. 1), although the average of allowed N dose still remain below.

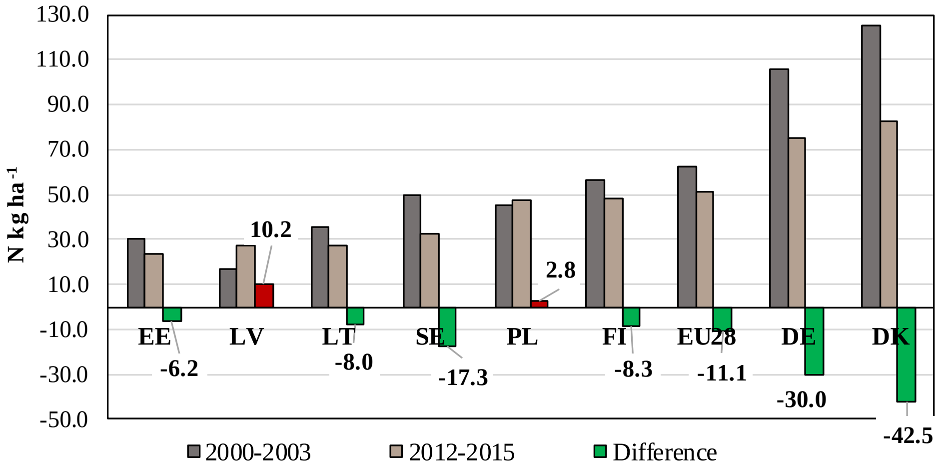

Figure 1. GNB and it changes in the Baltic Sea countries, 2000-2003 and 2012-2015
Source: authors' elaboration based on EEA, 2018

A surplus of N indicates potential climate change through: emissions of GHG (N_2O) and ammonia; and N leaching, which increase soil degradation process. High N inputs tend to decrease biodiversity (i.e., soil) within and outside the farmed area (Tsiafouli et al., 2015; D'Acunto et al., 2018; EEA, 2018).

Another important indicator—nitrogen use efficiency (NUE)—total N outputs (as yield) divided by total N inputs provides an indication of utilisation of N (EU Nitrogen Expert…, 2015; Eurostat, 2018). It may be useful to evaluate different strategies' contribution towards utilisation of N.

The highest value of NUE does not mean the best result. Rates that may be close to or above 1.0 would indicate a risk of soil depletion, as the N uptake by crops exceeds the amount of N applied to the soil, and cannot be considered sustainable (EU Nitrogen Expert…, 2015). NUE changes among the EU countries between periods 2000-2004 and 2010-2014 show that only in four EU countries, including Latvia, NUE decreases (Fig. 2).

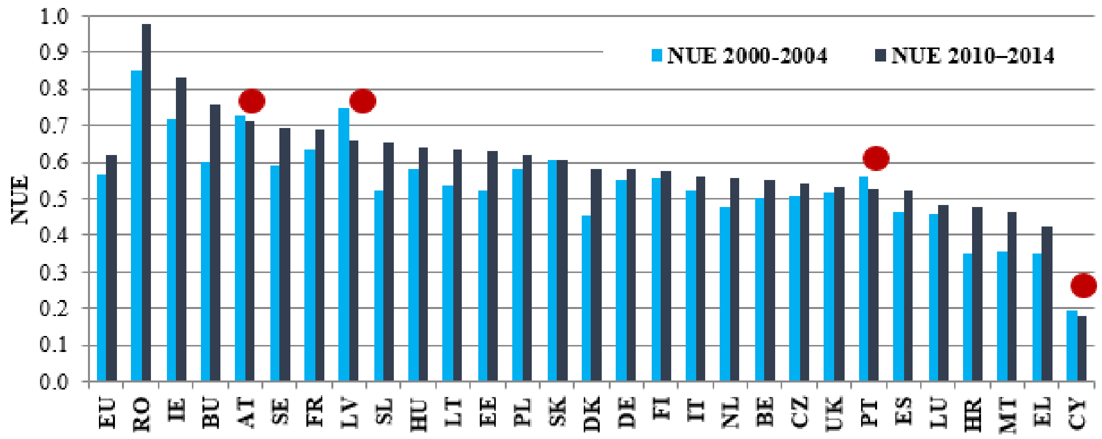

Figure 2. Nitrogen use efficiency and it change in the EU countries, 2000-2004 and 2010-2014

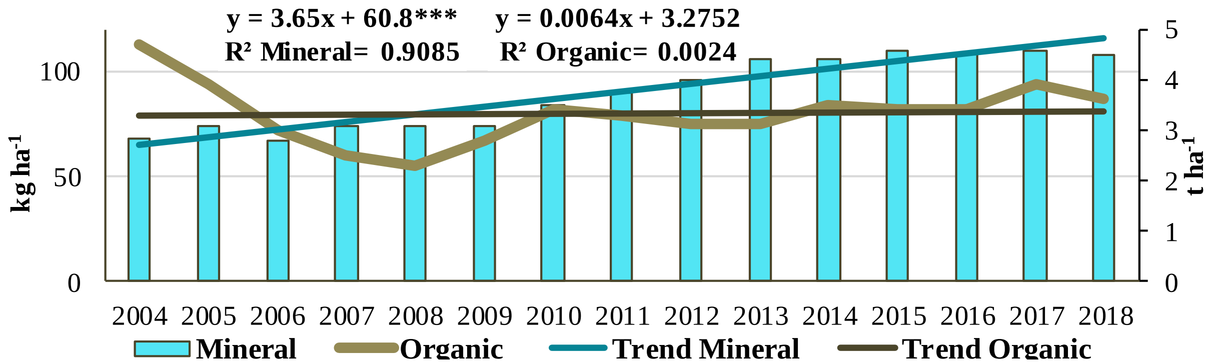
Source: authors' elaboration based on Eurostat, 2018

A range of preferable NUE is between 50% and 90% (0.5-0.9), where lower values increase potential N losses, but the higher values risk mining of soil N stocks or reserves (EU Nitrogen Expert…, 2015). NUE allows assessing agricultural production systems in terms of resource use efficiency, productivity, and environmental impact at the same time (Brentrup & Lammel, 2016).

In Latvia negative impact of agricultural intensification (i.e., monoculture, specialization of farming—crop farming, crop rotation disregard, decrease of crop diversity, etc.) causes significant increases of mineral N fertilizer usage (Fig. 3).

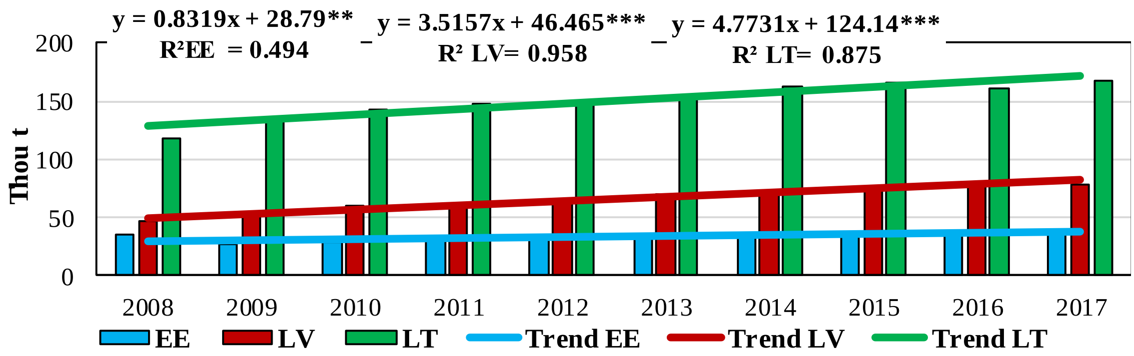


*** - α<0.01

Figure 3. Usage of mineral nitrogen fertilizer (kg) and organic fertilizer (t) per ha of sown area and it trends in Latvia, 2004-2018

Source: authors' calculation based on CSB data

Notwithstanding in all Baltic States the significant increase of mineral N fertilizer's consumption is detected, a more obvious trend is observed in Latvia (Fig. 4).



** - α<0.05; *** - α<0.01

Figure 4. Consumption of mineral N fertilizer and it trends in the Baltic States, 2008-2017
Source: authors' calculation based on Eurostat data

As result of agriculture intensification the diversity of crops decreased; and noticeably increased the production of most marketable crops, i.e., used as energy crops. Wheat and rape are exported, but green maize is used for biogas production. Moreover, growing tendency toward expansion of commercial monocultures is observed (Table 1).

Table 1. The changes of various crops' area from 2005 to 2017

Crop	Sown area, thou ha		Changes 2017/2005, %	
	2005	2017		
Winter wheat	129.1	331.2	**157%**	↑
Rye	45.1	34.0	-25%	↓
Spring wheat	55.4	140.4	**153%**	↑
Winter triticale	13.3	7.0	-47%	↓
Spring barley	145.9	78.2	-46%	↓
Oat	58.0	70.9	22%	↑
Buckwheat	10.4	30.9	197%	↑
Mixed cereals and pulses	8.1	5.3	-35%	↓
Field beans	0.4	42.5	**10525%**	↑
Winter rape	22.9	90.0	**293%**	↑
Spring rape	48.5	27.3	-44%	↓
Fodder roots	3.8	0.2	-95%	↓
Potatoes	45.1	22.7	-50%	↓
Open field vegetables	12.9	8.0	-38%	↓
Forage crops	372.2	297.6	-20%	↓
Perennial grass	360.6	270.3	-25%	↓
Crops for green feed & silage	8.7	1.6	-82%	↓
Maize for silage & green feed	2.9	25.7	**786%**	↑
Green manure crops	3.7	0.6	-84%	↓

Source: authors' elaboration based on CSB data

Dramatic increase of field beans' cultivation in Latvia, was encouraged by the introduction of green payments of the CAP. A similar tendency is observed in other EU countries. Implementation of such kind 'greening' measures has been criticised by scholars and experts, i.e., on EU level (ECA, 2017), because restriction or ban to use pesticides in greening areas lacking. Besides, it is recognised on EU level that Latvia's implementation choices for the CAP 2014-2020 involved political and historical factors, and was influenced by significant lobbying from the farmers' side (Ecorys, 2016). In particular, large farm owners.

Analysing recommended measures, we conclude that main part of them are noted as mandatory or voluntary requirements in RDP. Due to limited space, most suitable for Latvia adaptation measures to climate change on farm level are reported as a summary (Table 2).

Agroecology, i.e., organic agriculture	Niggli et al., 2009; Ferguson & Lovell, 2014; Tittonell, 2014; Kazakova-Mateva & Radeva-Decheva, 2015; Richards et al., 2015; Hart et al., 2016; EEA, 2019; IPCC, 2019

Conclusions

CAP policy and RDP measures regarding climate change and environment issues have various support to farmers to implement measures oriented to mitigate and adapt to climate change, as well as requirements such as Good Agriculture Practice, which should be fulfilled to receive payments. Nevertheless, proper nitrogen management, prevention of biodiversity decline, and soil and land degradation, etc., and related farming practices are not implemented or are implemented unsuccessfully. Since CAP (i.e., financial support) should contribute to soil, climate and biodiversity targets, it is necessary to develop more precise rules, requirements and procedures to receive green and agri-environment payments.

CHEMICAL COMPOSITION OF FLOODPLAIN SOILS OF THE LOWER DNIESTER RIVER

Tamara LEAH*, Nicolai LEAH

Institute of Pedology, Agrochemistry and Soil Protection "Nicolae Dimo", Chisinau, Republic of Moldova
*Corresponding author: tamaraleah09@gmail.com

Abstract

The chemical composition of the floodplain soils are caused by erosion-accumulative activity of the river and the nature of the basin soil cover. As a result of biogenic accumulation in the uppermost horizon of the soil, in addition to organic matter, a number of chemical elements are concentrated. The Dniester floodplain accounts for more than 50 thousand hectares. With a relatively low content of organic matter, the Dniester floodplain soils differ in significant humus reserves, which is associated with a large capacity of humiferous horizons in both modern and buried soils. In the 0-10 cm soil layer, the humus content is about 2.0%; in the 20-40 cm - 3.0%, with a gradual decrease to 0.5% at a depth of 185 cm. The soils of the Dniester floodplain are carbonate. The carbonate content (up to 7.5%) is inversely related to the amount of clay particles (<0.001 mm). The largest amount of SiO_2 is 56-81%. Alluvial silty-loamy riverbed soil contains 62.6-81.4% of SiO_2 in the layer with the highest silt content. Despite the light soil composition, the total P_2O_5 content is relatively high - up to 0.23%. The distribution of Na_2O is more uniform in soil - 0.8%. The soils are a high content of CaO (4-6%) and MgO (2.0-2.4%). Compared to the soils of the terraces, the floodplain soils contain a significant large number of nutrients - K_2O and P_2O_5.

Keywords: *Chemical composition, Dniester River, Floodplain soils, Moldova.*

Introduction

Lower Dniester is a protected area of the Republic of Moldova, a wetland of international importance. The total area is 60.000 ha (Kuharuk & Leah, 2017). In the floodplain of the Dniester river the whole range of alluvial soils is found, and in the valleys - diluvial soils. There are more than 60 of soil varieties registered in the floodplain of Dniester River (Sulin, 1970). The alluvial (meadow) soil is a representative one in the soil cover of the area. Flood meadow soils are new formations of alluvial soil. The alluvial processes include on the one hand the erosion of the riverbed, which causes the periodic "rejuvenation" of the riverbed and the adjacent sectors of the meadow, and on the other hand accumulations on the meadow surface the solid drainage of the river. In the Dniester meadow occurs the periodic flooding of its meadow with water from the river; in such cases the soils and the entire layer of alluvial deposits are considerably moistened. An important feature of alluvial soils is their high biogenesis, conditioned by the acceleration of the circuit of substances and the process of soil genesis (Leah, 2014; 2018b). The chemical composition of floodplain soils is determined not only by the processes of the floodplain soil formation, but to a large extent by the erosion-accumulative activity of the river and the nature of soil cover of its basin (Zakharova, et al, 2018). As a result of biogenic accumulation, in the uppermost soil horizon, in addition to organic matter, a number of chemical elements are concentrated, most of which are necessary for plant nutrition (Zakharova, et al, 2018). But this topsoil is primarily eroded. In Moldova, up to 50 tons of soil are washed off from 1 ha of cultivated slope lands in some cases, with which a large amount of humus and other substances is lost annually. These substances in the composition of solid and liquid runoff of the river are carried to the Black Sea (Kuharuk & Leah, 2017). Some of them accumulated in the sediments of the bases of slopes, beams and ravines, small river floodplains. Settling in completely different conditions, they become the arena of a new process of soil formation. Floodplain soils in Moldova occupy about 250 thousand hectares, which is 8.5% of the entire territory of the republic. Along with the researches on the zonal (principals) soils of Moldova, research is also being carried out on the floodplain soils (Leah, 2018a; 2018c; Leah, et al., 2018). However, many questions are not fully disclosed, since the soil of the floodplains is a very heavy object for research. In particular, little attention was paid to studying the chemical composition of these soils. The conditions of soil formation throughout the floodplain vary within the widest limits. Soils of all stages of hydromorphism are widespread here: from primitive underwater soils to steppe - meadow and forest - meadow soils, which are represented by different varieties of mechanical composition. Features of the mechanical composition are determined by the conditions of sediment deposition in the main geomorphological areas of the floodplain (Leah, et al., 2018). The lighter ones are confined to the riverbed area, the heavier ones are associated with the central area and terraces. In this regard, the soils developing on these sediments are differentiated by mechanical composition from the riverbed to the root bank and from the head of river to the mouth of the river.

The research purpose - to study chemical composition of the floodplain soils for their use in sustainable agriculture.

Material and methods

Recently, studies have been conducted on the chemical composition of the Lower Dniester river floodplain soils. A fully developed floodplain consists of three geomorphological parts or areas; the near riverbed, the central or plain, and the near-terrace (flat-lowered). In the near-river area of the floodplain, the most active is the alluvial process and minimally - floodplain process. Alluvial light soddy layered, often roughly stratified, soils arise here. In this area the alluvial light soddy stratified soils are formed, often coarsely - stratified soils. The area - is 13.3 thousand ha. Profile 1 (P1): *Alluvial-soddy, stratified, silty-clayey soil.*

The central area of the floodplain is characterized by the calm passage of flood waters. They attract mainly fine fractions of fine material - dusty and silty particles. Here alluvial-soddy granular and soddy granular gleyed soils are formed, which are most favorable in their properties for cultivating meadow grasses, planting vegetables and other crops. Their area is 22 thousand hectares. Profile 2 (P2): *Alluvial granular, clayey soil.*

In the near-flat lowland (near-terrace) area of the floodplain, clayey and colloidal particles gradually settle from the slowly flowing waters, flooding with a powerful layer the entire lowered territory of this part of the terrace. Under such conditions, the most severe medium- and heavily gleyed soils are formed. Their area is about 13.5 hectares. Profile 3 (P3). *Alluvial meadow, clayey - loamy, gleyed soil.*

Soil samples were taken from the most characteristic profile layers to the level of groundwater. Soil research occupies about 80% of the entire floodplain area and is characterized these three genetic areas: near-riverbed, central, and near- terrace.

Chemical composition includes determining of the hygroscopic water content, loss of calcinations, and the content of elements that make up the mineral part of the soil: Si, Al, Fe, Ca, Mg, Na, K, P, S, Ti, Mn. The sum of the oxides of these elements is usually more than 99% of the mineral part of the soil. In the carbonatic soils, in addition, the content of CO_2 carbonates is determined. Total composition of analyzed elements is determined by the classical method.

Results and discussions

The soils of the Dniester floodplain are low-humus. However, with a relatively low content of organic matter, they differ in its significant reserves, which is associated with the large thickness of the humus horizons of both modern and buried soils. The distribution and content of humus along the profile is uneven and is primarily due to the influence of energy material of different mechanical composition deposited by the river during the flood.

The smallest reserves of organic matter are characterized by the soil of the near-riverbed (P1), where they are formed on a light, low-humus riverbed alluvium. In the 0-15 cm layer, the humus content is about 2.0%, in the 20-40 cm layer it reaches 3.0% with a gradual decrease to 0.5% at a depth of 185 cm. Even lower the amount of humus increases again and at about a depth of 300 cm is 1.8%. Such a distribution reflects only the lithological (granulometric) stratifying of the soil profile and is not related to the modern process of soil formation.

The mechanical composition of the soil (texture, granulometric composition of soil) is the content in the soil of elementary particles of different sizes. This is one of the leading environmental (regulatory and limiting) factors on which other soil properties also depend - moisture capacity, porosity, thermal stability, and consequently, the soil fertility.

So, in the layer of 0-10 cm the content of particles <0.001 mm is 16% in P1, 32% - P2 and 48% - P3. In a layer of 90-100 cm - 14%, 37%, 58%, below the mechanical composition is gradually lightened, and then heavier again. In the Profile 1 the stratification is clearly highlighted; in the P2 - the composition indices are evenly distributed on the whole depth; and in the P3 - a slightly uniform distribution up to the depth of 150 cm, from the 160 cm stratification is evidently (Figure 1, 2, 3).

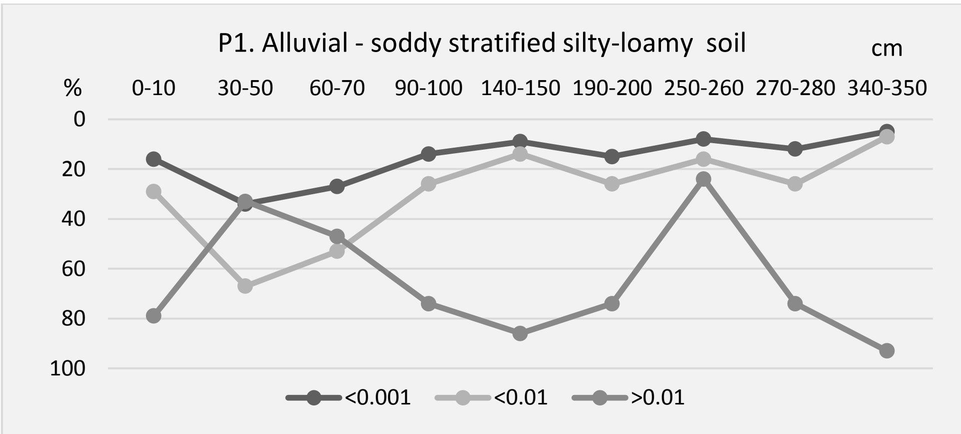

Fig.1. The fraction composition (<0.001, <0.01, >0.01) of Profile 1.

The soil from central floodplain in terms of mechanical composition is heavier and more homogeneous. The humus content is higher, and its distribution along the profile is more even. A layer of 0-10 cm contains 4.4% of humus; in a layer of 10-60 cm - 3.5%, below its amount, as the mechanical composition is facilitated, decreases in heavier layers.

The studied soils of the Dniester floodplain are carbonated. The carbonate content is inversely related to the amount of silt particles (<0.001), as well as the soils are mechanically layered so that their distribution along the profile is uneven. This is especially noticeable in stratified soils (P1), in the profile of which several maxima of carbonates are observed. In light layered soils of the near-terrace, the distribution of $CaCO_2$ is more uniform and content is highest.

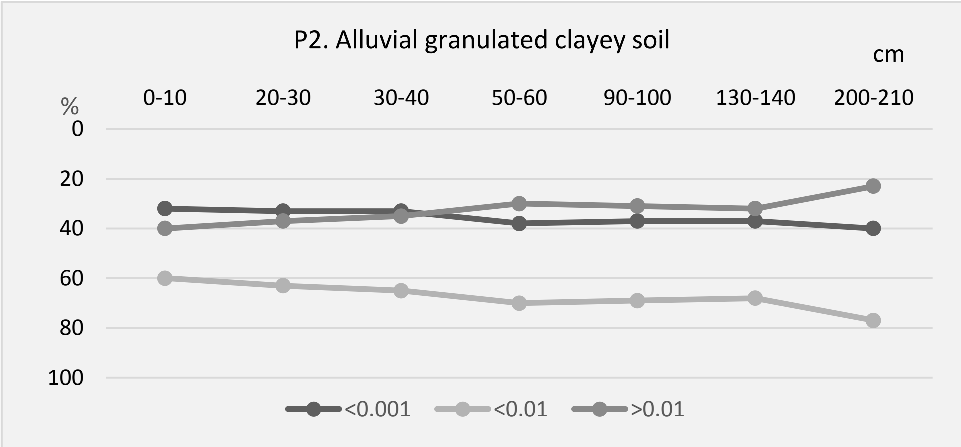

Fig.2. The fraction composition (<0.001, <0.01, >0.01) of Profile 2.

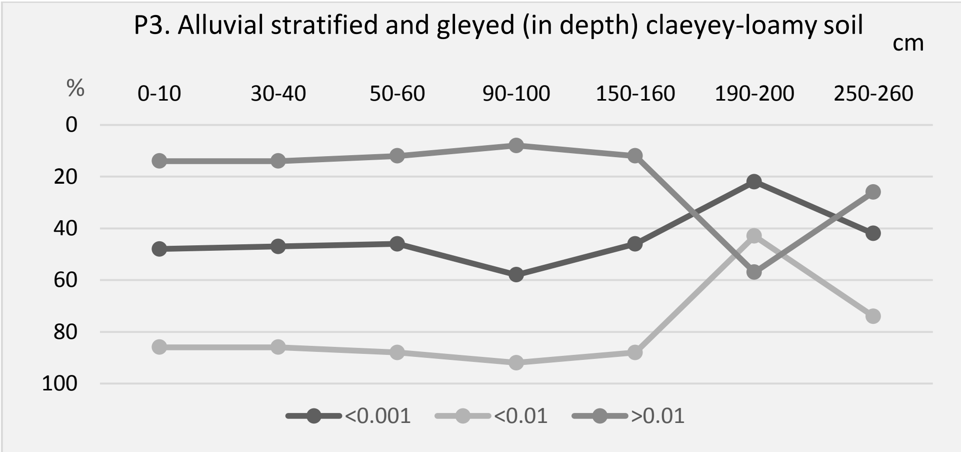

Fig.3. The fraction composition (<0.001, <0.01, >0.01) of Profile 3.

In soils with a homogeneous mechanical composition, according to the content of individual elements of the aluminum-silicate part, can be traced the presence or absence of mineral destruction processes and the profile movement of destruction products. In contrast its, the granulometric heterogeneity of the soil profile of floodplain soils makes it difficult to identify changes in their chemical composition that have occurred as a result of soil formation, and makes it possible only to ascertain the presence of an element in individual layers of the profile. The content of most elements in soil and alluvial deposits depends mainly on the mechanical composition. In this regard, their distribution in the soils of floodplain areas, as well as in the profile of individual soils, is uneven.

The greatest amount of SiO_2 is observed in the soils of the riverbed (P1). So, for example, in layers of 250-260 cm, where particles <0.001 mm contain 8%, the amount of silicon reaches 76%. In the layer of 140-150 cm, where silt particles account for 9%, its content drops to 78%. The near-terrace soil (P3) contains less SiO_2 with a minimum of 56.2% in the layer with the highest silt content - 46%. The soils of the riverbed also have a high content of calcium (4.1-5.6%) and magnesium (1.3-2.1%). The distribution of these elements along the all profile varies relatively little - 3 - 6% (CaO) and 1.2 - 2.1% of (MgO). Compared to the soils of the central and riverbed area the near-terrace soil (p3) is characterized by a lower content of elements - MgO, CaO, and highest content of Al_2O_3, Fe_2O_3, K_2O, P_2O_5, TiO_2 (Table 1).

LAC*- losses after calcinations. The LAC are used to calculate the total content of minerals in the soil and recalculate the content of nutrients in the mineral part of the soil to a calcinated sample.												

The titanium content in soils is distributed relatively uniformly along the profile. In a layer of 60-70 cm, its amount reaches 0.6% (P1). In clayey (P2) and clayey-loamy soil (P3) the TiO_2 content is higher and is clearly dependent on the size of the silt fraction. Despite the heavy composition of these soils, the total P_2O_5 is relatively high and ranges from 0.15-0.30%.

Soils of the near-terrace floodplain contain less SiO_2, compared with near-riverbed. The amount of it, even in the layers of the most light mechanical composition does not rise above 61% (P3). One and a half oxides are much larger. The distribution of the listed elements along the profile is quite uniform, especially in soils with a uniform mechanical composition (P2). The content of calcium and magnesium is slightly lower, and phosphorus, potassium and sulfur are much higher. In some layers, the amount of P_2O_5 reaches 0.27%.

The uniform distribution of Na_2O in all alluvial soils, on average not exceeding 0.9% (P1, 0-10 cm) is noteworthy. However, in soil (P2 and P3, 0-10 cm) is 0.72% and 0.59%. Such a sharp increase in this element in the upper horizon is explained by sodium sulfate salinization.

The soil of the near-terrace area (P3) is characterized by the lowest content of SiO_2 - 59.6%, and the highest content of Al_2O_3 - 15,7% or 1,8 times more than in P1 (0-10 cm). Calcium and magnesium are less here, and K_2O, SiO_2 and P_2O_5 are slightly more. All other elements are evenly distributed along the profile (Table 1).

An analysis of the latest alluvial deposits shows that the content of many elements in them corresponds to the content of those in the soils that are formed on them. The distribution and content of chemical elements in the soils of the Dniester floodplain is not uniform in profile and tends to repeat the regularity of the physical clay content. Soils of the riverbed and central floodplain are most enriched with elements compared with near-terrace floodplain soil. The distribution and content of total elements along the profile of the studied soils is in accordance with stratification and depends on the mechanical composition.

Conclusions

The forming soils in the Dniester floodplain are confined to zones of accumulation of energetically material carried away from the watersheds and slopes of the river basin. Differentiation of alluvial deposits according to the mechanical composition in the floodplain, from the riverbed to the root bank entails the differentiation of floodplain soils in the same direction. The accumulation of humus, phosphorus, potassium and other nutrients is mainly due to input from the outside and only part of them is formed as a result of the soil formation process in the floodplain itself. An increase in the content of many chemical elements in the floodplain soils is observed from near-riverbed area to near-terrace and downstream of the river. Compared to the zonal soils of the river basin, in its floodplain, the soils contain a significantly larger number of nutrients.

Abstract

The biological diversity of an ecosystem is a good indicator of its quality and its capacity to resist deterioration due to the external factors. The biodiversity conservation is a key element of environmental protection. The aim of this work was to evaluate the physical, chemical and biological characteristics of soils under oléastre in Kabylian region Algeria. We sampled soil of seven shrubs on four levels. The physical and chemical soil parameters as well as the enumeration of the soil fauna according to Berelèse-Tullgren method on four levels were measured. Soil was a cambisol (W.R.B. 1998). To do so, soils as well as soil invertebrates were analysed. The soil was silty loam and with sandy texture, with a slightly acidic to neutral pH, with low rates of organic carbon by means against the levels of available phosphorus are very low. This count allowed us to examine six orders of animals, springtails, beetles, annelids, nematodes, centipedes and beetles larvae. This work showed that the environmental conditions, in particular soil characteristics, hadan important impact on the presence and/or absence of certain soil invertebrates. The main result of this work lies on the hierarchization of factors driving invertebrate communities in Kabylian soils. However, the composition of soil fauna should be considered for rehabilitation. The results presented in this study are valid for this region only. To make a more general statement about the results, this type of studies needs to be applied to different soils, orchards and other climates in Northern Africa.

Introduction

Soil is a natural resource that represents all the products of physical degradation and then chemical alteration of the parent rock (Deprince, 2003). It consists of three phases ;a solid phase consisting of an inorganic fraction and an organic fraction; a liquid phase and a gaseous phase. Soil fauna presents an important taxonomic diversity, it is currently estimated at more than 23% of the animal biodiversity described today (Lavelle et al., 2006). These living beings are indicators of soil quality and should be considered as a resource for improving ecosystems (Boudiaf NaitKaci, 2014).African wild olive is a valuable tree in the dry Afro-montane forest, capable of regenerating naturally (Arests et al., 2006). This shrub generally grows on relatively poor soils with rugged terrain, in semi-arid zones with temperate climates, such as in southern Spain and northern Africa, it can also be found on the banks of streams temporary (Durand and Terral, 2006). The olive tree counts among the most important oil-producing crops throughout the Mediterranean region. The century-long presence of olive trees in most producing countries can lead to misunderstanding as to the sustainability, hardiness, longevity and plasticity of their cultivation. Soil management in olive has been oriented for centuries to insure productivity and survival of the plantation under conditions of limited, and highly variable, rainfall using a combination of low plant density, limitation of tree canopy size by pruning and elimination of adventitious vegetation to limit competition for soil water (Fernández-Escobar et al., 2013).

The aim of the present work was to hierachize factors recognized as important drivers for soil invertebrate community: the physical, chemical and biological soils characteristics under *Olea europeae* sub sp *sativa*in Kabylian region Algeria. We hypothesized that soil invertebrates are controlled by interactions between these three factors.

Material and methods

Study sites

Olea europeae sub sp *sativa* population has been selected in TiziRached Northern Algeria (36° 41'71" N ; 4°12'39,27" E), the altitude is 216 m.Our study site is a 70-year-old olive grove, where the oleaster has settled spontaneously following a fire in olive-growing orchards a decade ago. It rests on a sandy mother rock.Climate is sub-humid and the dry period begins in June and ends in September.

Soil sampling and characterization

The soils were Cambisols (WRB, 1998). Sampling was carried out on seven *Olea europeae* sub sp *sativa*, on four depths, the trees were chosen according to the vegetation cover and the homogeneity of the lithotopesquence. Soil sampling in January 2016, on four levels : h1 (0-10 cm), h2 (10-20 cm), h3 (20-30 cm) andh4 (30-40 cm).

Soil characteristics were determined according to standard methods proposed in Jackson (1967). Particle size distribution was measured according to the Robinson pipette method (*i.e.* organic matter oxidation by H_2O_2, shaking in a sodium hexametaphosphate solution). Soil pH was measured in a 1/5 soil distilled water suspension. The $CaCO_3$ content was determined using the HCl 1M volumetric method. Organic C was determined by sulfochromic oxidation. Bioavailable phosphorus was extracted by shaking soil samples in $NaHCO_4$ 0.5 M solution at pH = 8.5 (soil/solution ratio of 1/10) during 1 h (Olsen in Jackson, 1967). The suspension was then filtrated and phosphorus concentration in the solution was determined by colorometry.

Invertebrate sampling and identification

Invertebrate samplings were done during winter 2016 following the methodology of Coineau, (1974). In each selected shrub, four depths were sampled (0-10, 10-20, 20-30, 30-40 cm). In the laboratory, large invertebrates were hand-sorted. Afterwards, remaining invertebrates were extracted from soil by Berlese-Tullgren method (Pesson, 1971). After extraction, all invertebrates were preserved in 70° alcohol for ulterior identification. Giving the low taxonomic expertise on Algerian soil fauna, invertebrates were indentified at order level in most cases.

Statistical analyses

Kruskal-Wallis rank sum test were used for testing soil differences between depths and trees. Afterwards, multiple comparisons were done to identify groups that differed (Siegel and Castellan, 1998). We also tested the influence of the factors 'soil', 'level' and 'shrubs' and their interactions on the density and the diversity of invertebrates. For this, analyses of variance were performed on log-transformed data. Tukey's 'Honest Significant Difference' method was used to test for means multiple comparisons.

Results and discussion

Soil characteristics

Soils have a silty-sandy loam texture. This is due to the presence of a sandstone bedrock (Rudel and Treilhou, 1974). Soils pH are neutral (fig. 1a). These variations can be due to the buffering capacity of the soils and the numerous reactions occurring therein, which regulate the actual acidity (Hinsinger et *al*., 2003). In the case of the studied soils, the passage of a fire and the destruction of the organic matter and the mineral substances found there reduce the acidity of the soil (Viro, 1974).

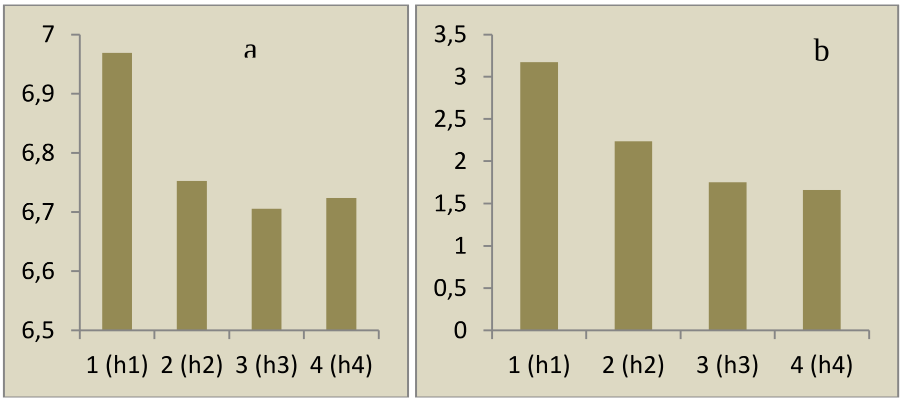

Figure 1. Mean soil characteristics of the 7 studied trees (a : pH ; b: organic matter)

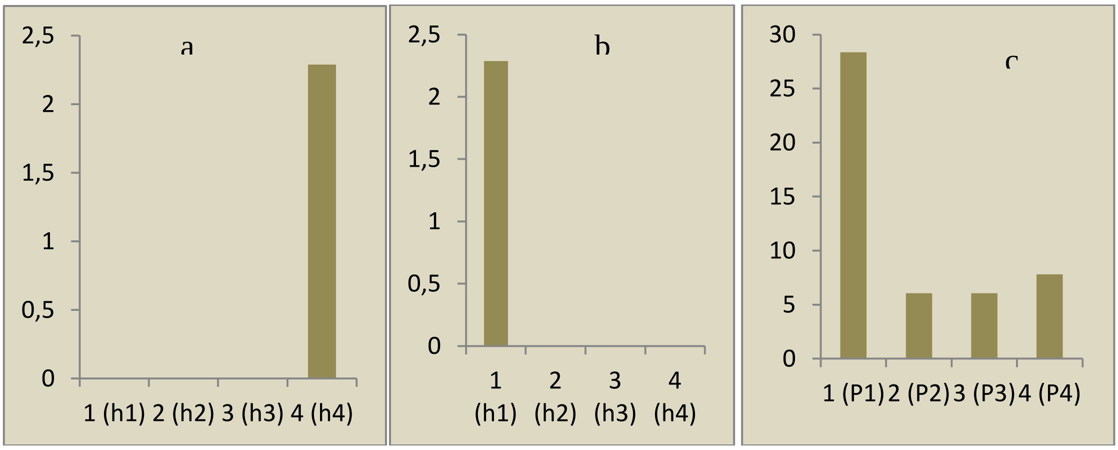
Organic carbon levels are low to medium (fig.1b). The lowest rates can be related to the degradation of the olive grove that has undergone fires. Pansu et *al*., (2009) demonstrated that fires cause loss of organic matter.The Olsen phosphorus contents are very low and vary between 0.483 and 1.32 ppm. This variation can be explained by the fact that the roots have an important part of the root system compared to its low diffusion to the soil and its slow transfer to the roots (Stengel and Gelin 1998 and Jaillard et al., 2000). A clear difference between 1st and 2nd level is to be noted, this may be due to the passage of a fire. Viro, (1974) reports that assimilable phosphorus is richer in the surface layers of the soil after the passage of a fire.

Invertebrate density and diversity

The enumeration of the invertebrates allowed us to count a total of 2240 ind / m^2, grouped in six orders. The annelids are strongly represented with a dominance of 48%, the myriapods comprise 20% of the elements recorded, the beetles are represented with a dominance of 14% of which 13% are represented by beetle larvae. On the other hand, nematodes and mites are less abundant, respectively 11% and 7% of the total population. Collemboles are weakly present with a 1% strength.

The invertebrate harvesting in the soils of this station has shown that collembola are present only in level 4 (fig. 2a). These invertebrates have adaptation to the deep layers of the soil, they are hydrophilic species and the lack of moisture causes. Their desiccation explains their abundance in level 4 because they shun heat towards the deeper habitats (Davet, 1996; Ait Mouloud, 2006).Coleopterans are observed only in the first level (fig. 2b). Deprince, (2003) showed that they are located particularly in the humic horizon and in the soil annexes.



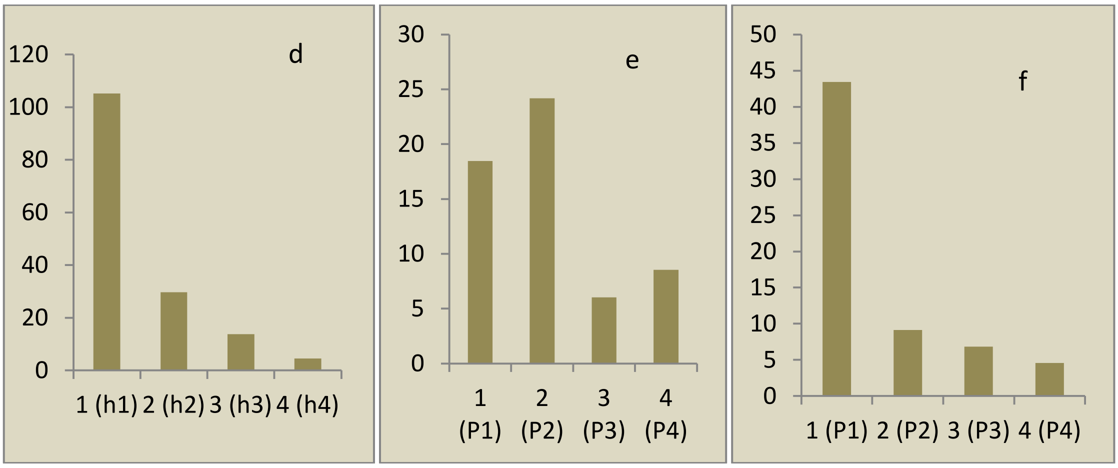


Figure 2. Mean density of invertebrates asa function of depth (a : Springtails ; b : Coleoptera ; c : Beetle larvae; d : Annelids ; e : Nematodes ; f : myriapods)

Coleoptera larvae are found mainly in the first ten centimeters of the soil nevertheless, they are also present in the 2nd, 3rd level, with a slight increase in the 4th level (fig. 2c). This is consistent with the fact that beetles show their influences in the soil by their larvae (Deprince, 2003; Gobat et *al*., 2003).

Annelids are very abundant by contribution to the other groups, they are distributed mainly in the first 10 centimeters of the ground, however they are present in depth (fig. 2d). Annelids descend to the depths in dry and wet periods, but remain active throughout the year (Abdul and Abdul, 1994). The works of Monroy (2006), show annelids prefer to live in decomposed logs. They contribute to litter decomposition and have a direct effect on nutrient mineralization (Morin, 2002). Nematodes are mostly present in the first 20 centimeters (fig. 2e), but also present in the other horizons, they are aquatic animals that live in the rhizosphere and decaying matter (Chaussod, 1996), which explains their displacement via leaching waters which can easily lead them deeply (Bachelier, 1978).

Myriapods are essentially concentrated in the top 10 cm of soil (fig. 2f)., which is consistent with the fact that they live in litter and play a very important role in the decomposition chain, or consume up to 25% of the litter (Gobat et *al*., 2003).

Hierarchy of factors

The main result of this work lies on the hierarchization of factors driving invertebrate communities in Kabylian soils. It clearly appeared that the factors soil and depth profoundly affected the total density of soil invertebrates. Based on the ACP it is found that there are significant values at the threshold of $\alpha = 0.05$ between annelids and pH, CO and myriapods and annelids (fig.3).

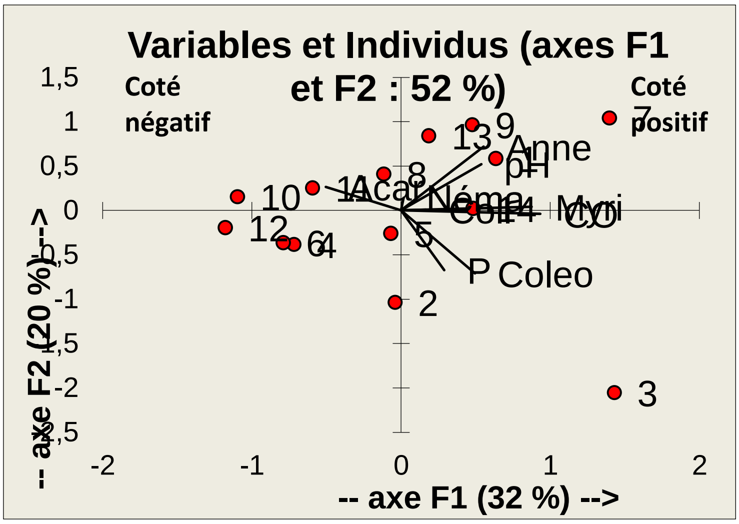

Figure 3. ACP

pH is a chemical constraint that largely influences the biological activity of soils (Davet, 1996), it intervenes in the presence and absence of fauna (Raphael, 2007), annelids prefer soils at pH between 5-7.4.Myriapods belong to the first trash compartment and live in litter (Gobat et *al*., 2003), while coarsely fragmenting organic matter (Deprince, 2003), hence the correlation between myriapods and organic carbone. The myriapods and annelids break down and fragment organic matter (Jungmann, 2014), which justifies their presence and their cohabitation in *Olea europaea* subsp *europaea* var *sylvestris* soils.

Conclusion

The objective of this work is a physical chemical and biological characterization of a soil under a population of *Olea europaea subsp europaea var sylvestris* appeared spontaneously after a fire. The morphology and description of the profile allow us to classify this soil as a Cambisol (WRB, 1998).This study gathers the original data concerning the abundance of invertebrate communities. It has shown in terms of variation and abundance that invertebrates are structurally different from one tree to another and from one level to another, Another in an oleo-lentisic ecosystem, which is a sign of degradation of Mediterranean soils. This census allowed us to examine six orders of animals: collembola, beetles, annelids, nematodes, myriapods and beetle larvae. We were interested in understanding the biofunctioning of this fragile environment as well as the vertical distribution of its fauna. Several factors have been considered to explain the distribution of invertebrates in these soils, without neglecting the impact of the fire on the physical, chemical and biological changes of this environment.Soil degradation, most frequently soil erosion but also a decrease of soil nutrients and organic matter, and soil compaction, is systematically quoted as one of the major threats to sustainability of oleaster.

CALIBRATION OF SALTMED MODEL FOR INDUSTRIAL TOMATO CULTIVATION IN CENTRAL GREECE USING A DRIP IRRIGATION SYSTEM

Maria KOKKORA, Antonios SIOURAS, Panagiotis VYRLAS, Dimitrios KALFOUNTZOS*

General Department of Larissa, University of Thessaly, Larissa, 41110, Greece

Abstract

Irrigation plays a key role in increasing agricultural productivity. Irrigated agriculture uses about 70% of global fresh water consumption. The continuing increase in world population and fresh water demands, along with the climate change effects are further threat for limited fresh water resources especially in arid and semi-arid regions. Models can be very useful tools in agricultural water management. They can help in irrigation scheduling and crop water requirements calculation and also to predict yields and soil salinization. Most of the existing models are designed for a specific irrigation system and are single-process oriented, such as models for water and solute movement, infiltration, leaching or water uptake by plant roots or a combination of them. SALTMED model has been developed for generic applications. In this research, the SALTMED model was calibrated using data from an industrial tomato cultivated field in Larissa region, central Greece, irrigated with fresh water at different water levels, using a drip irrigation system, corresponding to 100%, 80% and 60% of ET_c (deficit irrigation). The model successfully illustrated the effect of the irrigation application on soil moisture distribution and crop yield.

Keywords: *SALTMED model, Crop yield.*

Introduction

Irrigation plays a key role in increasing agricultural productivity. As a matter of fact, agriculture is the largest water user worldwide. Irrigated agriculture uses about 70% of global fresh water withdrawal (FAO, 2017). The continuing increase in world population and fresh water demands, along with the climate change effects are further threat for limited fresh water resources especially in arid and semi-arid regions (Lekakis and Antonopoulos, 2015). Improving agricultural productivity, while conserving natural resources as water, is essential for sustainable food production. Models can be very useful tools in agricultural water management. They can help in irrigation scheduling and crop water requirements calculation and also to predict yields and soil salinization. Most of the existing models are single-process, oriented, such as: a) models for infiltration (Bresler, 1975; Vogel and Hopmans, 1992), b) models for root water uptake (Cardon and Letey, 1992a; Coelho and Dani, 1996), c) models for leaching or water and solute transport (Antonopoulos, 1997; Vanclooster et al., 1996; Babajimopoulos *et al*., 1995; Cardon and Letey, 1992b), or d) models for specific applications, i.e. certain irrigation system, soils, region or a crop (Noborio *et al*., 1996; Minhas and Cupta, 1993; Cardon and Letey, 1992b; Ragab *et al*., 1990).

The SALTMED model is a comprehensive generic model (Ragab 2002, 2005, 2015) that can be used to predict final yield, dry matter, soil moisture and soil salinity profiles, plant water and nitrogen uptake, soil nitrogen transformation and content, drainage flow and evapotranspiration. The model is suitable for rainfed and irrigated agriculture, as well as for different irrigation systems and irrigation strategies, and it accounts for the presence of drainage systems and shallow groundwater. Moreover, the model can handle different crops, soil types and N-fertilizer applications.

One of the most demanding crops for irrigation is the industrial tomato, as it requires approximately 600 mm water per year. Consequently, the optimization of the irrigation conditions of the industrial tomato production is of paramount importance.
The objective of the present study was to calibrate the SALTMED model according to the soil moisture and crop yield results obtained for an industrial tomato crop cultivated on a sandy clay loam soil in central Greece, using drip irrigation with fresh water, with amounts of water equal or less than the full crop requirements (deficit irrigation).

Material and Methods

A field experiment was established at the farm of University of Thessaly in Larissa, central Greece. The soil at the experimental site was a sandy clay loam. Industrial tomato (*Heinz S3402*) was transplanted at the stage of 6-7 real leaves, on 1st and 2nd of May 2012. Each experimental plot contained 4 crop rows, spaced 1.05 m apart. The dimensions of each experimental plot were 3 m x 5 m (15 m^2). Industrial tomato was irrigated with fresh water. Three irrigation levels (treatments) were applied representing 100%, 80% and 60% of the design irrigation depth. Table 1 shows the amount of water applied, as irrigation water and total water (sum of irrigation plus rainfall). The experimental plan included randomized groups with four replicates.
The irrigation network consisted of a main delivery PE ∅32 pipe and three PE ∅20 secondary ones (one for each treatment). The 16-cm in diameter drip lines of the drip system were 5 m in length and spaced 1.5 m apart, with built-in pressure-compensating and self-cleaning emitters, spaced 0.70 m apart, with a flow rate of 2.2 L h^{-1} at an operating pressure range of 0.5 to 3.5 bars, with a double self-cleaning mechanism and two outlet channels to prevent clogging. The irrigation system control unit consisted of a collector equipped with 3 electric valves connected to an irrigation controller and 3 water meters. Each valve with its water meter was connected to the secondary pipes, each one of them fed four experimental plots. Each experimental plot contained 2 drip lines. The depth of the water applied was calculated from the readings on the water meters and the area of each experimental plot.
Crop harvest was carried out at the red maturation stage according to the USDA (1997) ranking, on 24th of August 2012, by hand. From each experimental plot, a total of 10 plants was harvested and weighed separately for each line. Crop yield was calculated.

Table 1. Total irrigation water and total applied water depths for each treatment (irrigation level).

Irrigation level	Irrigation water (mm)	Total water applied (mm)
100% ET_c	587.18	697.00
80% ET_c	469.74	580.14
60% ET_c	352.31	462.71

The version of SALTMED model that was used in this study is the one presented by Ragab (2015) version 2019. A detailed description of the SALTMED model is provided in Ragab (2002; 2015). Some key parameters of the model are presented below.
Crop evapotranspiration ETc was calculated as:

$$ET_c = ET_0 (K_{cb} + K_e) \quad (1)$$

where K_{cb} is the crop transpiration coefficient and K_e the bare soil evaporation coefficient. The values of K_{cb} and K_c, (the crop coefficient) for each growth stage, and the length of each

growth stage for large number of crops, are available in the model's database. K_e is calculated as the difference between K_c and K_{cb}.
Evapotranspiration (ET_0) has been calculated using the Penman–Monteith equation according to the modified version of the equation by the Food and Agriculture Organization of the United Nations (FAO) (Allen et al., 1998):

$$ET_0 = \frac{0.408\Delta(R_n - G) + \gamma\frac{900}{T+273}U_2(e_s - e_a)}{\Delta + \gamma(1 + 0{,}34U_2)}$$
(2)

where ET_0 is the reference evapotranspiration (mm day^{-1}); Rn, the net radiation (MJ m^{-2} day^{-1}); G, the soil heat flux density (MJ m^{-2} day^{-1}); T, the mean daily air temperature at 2 m height (°C); Δ, the slope of the saturated vapour pressure curve (kPa $°C^{-1}$); γ, the psychrometric constant, 66 Pa $°C^{-1}$; e_s, the saturated vapour pressure at air temperature (kPa); e_a, the prevailing vapour pressure (kPa); and U_2, the wind speed at 2 m height (m s^{-1}).
Actual water uptake rate has been calculated based on the formula suggested by Cardon and Letey (1992), which determines the water uptake S (mm day^{-1}) as follows:

$$S(z,t) = \left[\frac{S_{max}(t)}{1 + \left(\frac{a(t)h + \pi}{\pi_{50}(t)}\right)^3}\right]\lambda(z,t)$$
(3)

where
$\lambda(z) = 5/\ 3L$ for $z \leq 0{,}2L$
(4)
$\lambda(z) = 25/\ 12L \times (1 - z/L)$ for $0.2L < z \leq L$
(4a)
$\lambda(z) = 0{,}0$ for $z > L$
(4b)

$S_{max}(t)$ is the maximum potential root water uptake at the time t; z, the vertical depth; λ, (z,t) the depth and time-dependent fraction of total root mass; L, the maximum rooting depth; π, the osmotic pressure head; h, the matric pressure head; $\pi_{50}(t)$, the time-dependent value of the osmotic pressure at which $S_{max}(t)$ is reduced by 50%, and a(t) is a weighing coefficient that accounts for the differential response of a crop to matric and solute pressure. The coefficient a(t) equals $\pi_{50}(t)/\ h_{50}(t)$ where $h_{50}(t)$ is the matric pressure at which $S_{max}(t)$ is reduced by 50%.
The potential water uptake $S_{max}(t)$ is calculated as:

$S_{max}(t) = ET_0(t) * K_{cb}(t)$
(5)

The rooting depth was assumed to follow the same path of the crop coefficient K_c and was therefore described as follows:

$$Root\ depth(t) = \frac{[Root\ depth_{min} + (Root\ depth_{max} - Root\ depth_{min}) \times K_c(t)}{K_{c\,max}}$$
(6)

The relative crop yield (RY) is estimated as the sum of the actual water uptake over the season divided by the sum of the maximum water uptake, i.e. the water uptake under no water and salinity stress, as:

$$RY = \frac{\sum S(x,z,t)}{\sum S_{max}(x,z,t)}$$
(7)

where x and z are the horizontal and vertical coordinates, respectively, of each point in the root zone that contain roots. The actual yield (AY) based on RY is calculated as:

$AY = RY * Y_{max}$
(8)

where Y_{max} is the maximum yield recorded in a given region under stress-free optimum conditions.

Results and Discussion

The SALTMED model was calibrated using data from an experimental field of industrial tomato cultivated on sandy clay loam soil at the farm of University of Thessaly in Larissa, central Greece, irrigated with freshwater. The meteorological data were taken from the Larissa meteorological station.

The plant coefficients k_c and k_{cb} were 0.6 and 0.18, respectively, for stage (1) of 33 days. During stage (2) of 40 days, they both increased linearly, k_c from 0.6 to 1.15 and k_{cb} from 0.18 to 1.1. During stage (3) of 45 days, k_c and k_{cb} were 1.15 and 1.1, respectively. At the final stage (4) of 27 days, both coefficients decreased linearly, k_c from 1.15 to 0.7 and k_{cb} from 1.1 to 0.7.

Crop parameters, such as the minimum and maximum depths of the root zone, which were 0.1 and 0.6 m, respectively, were determined by field measurements. Soil parameters, such as saturated hydraulic conductivity were also obtained from field measurements, while the characteristic curve of the soil was determined in the laboratory. Soil water characteristic curve in conjunction with the RETC program (Van Genuchten et al., 1991), were used to calculate parameters such as the residual moisture content θ_r and the saturation moisture content θ_s. Their values were found to be 0.54 and 0.003, respectively. The parameters, α, n and λ (soil resource allocation coefficient) were found to be 0.0012, 1.3 and 0.3, respectively. The bubbling pressure value used by the program database for sandy clay loam soil was 37.037 cm. Volumetric moisture content measurements were carried out using the Trime device, which operates with the TDR method.

Figure 1 shows the evapotranspiration of the crop, the crop transpiration and the bare soil evaporation throughout the growing season in the year 2012. Figure 2 presents the simulated by the SALTMED model industrial tomato yield, indicatively for the treatment of 100% ET_c, as well as the actual and dynamic intake of water by the plants' roots. As shown in Figure 2, the maximum crop yield was set at 100 tn/ha and was reduced accordingly to the water stress.

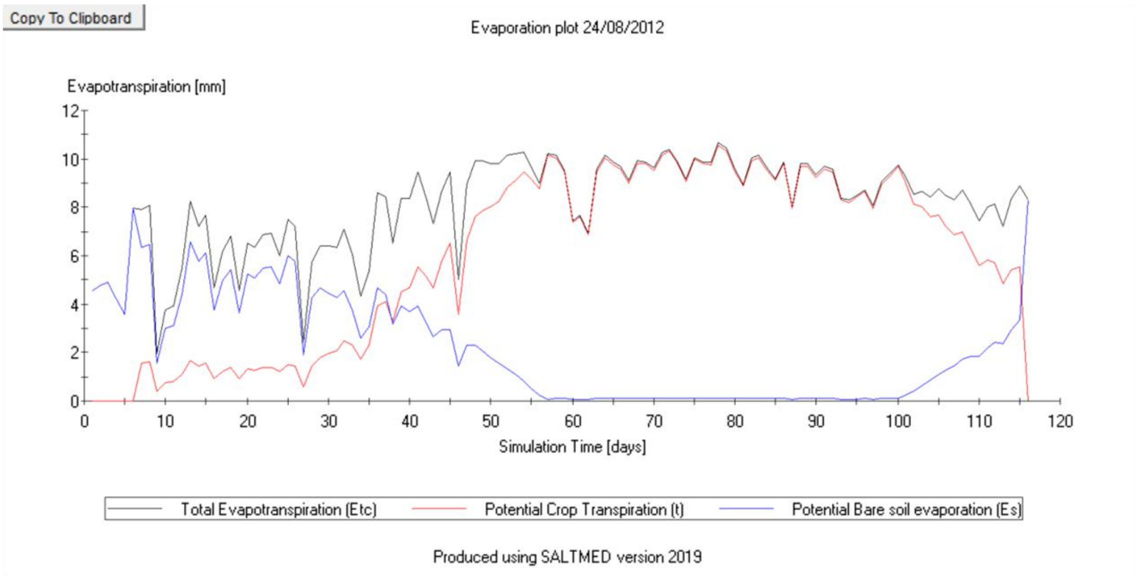

Figure 1. Evapotranspiration, crop transpiration and bare soil evaporation.

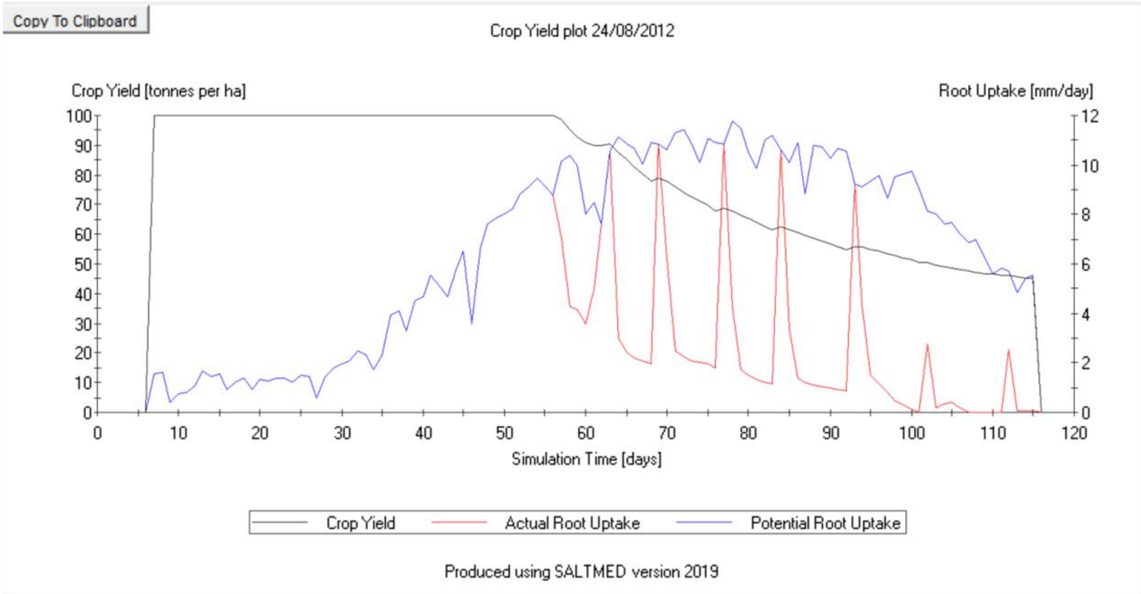

Figure 2. Simulated industrial tomato yield by the SALTMED model for the treatment of 100% ET_c.

Industrial tomato yield, simulated and measured, for each treatment is presented in Figure 3. The simulated tomato production values do not deviate from the measured ones, at all levels of irrigation tested, thus suggesting that the SALTMED model can simulate well industrial tomato yield. Also, the results illustrate different yields under different irrigation strategies. The more deficit irrigation strategy resulted in the lower yield, suggesting that industrial tomato is indeed a highly water-demanding crop and irrigation water reductions up to 20% of ET_c can reduce crop production by about 28%. Therefore, other irrigation strategies, such as the use of treated wastewater, or saline water, should be considered in order to achieve fresh water savings whilst ensuring maximum industrial tomato yields to meet the future food demand.

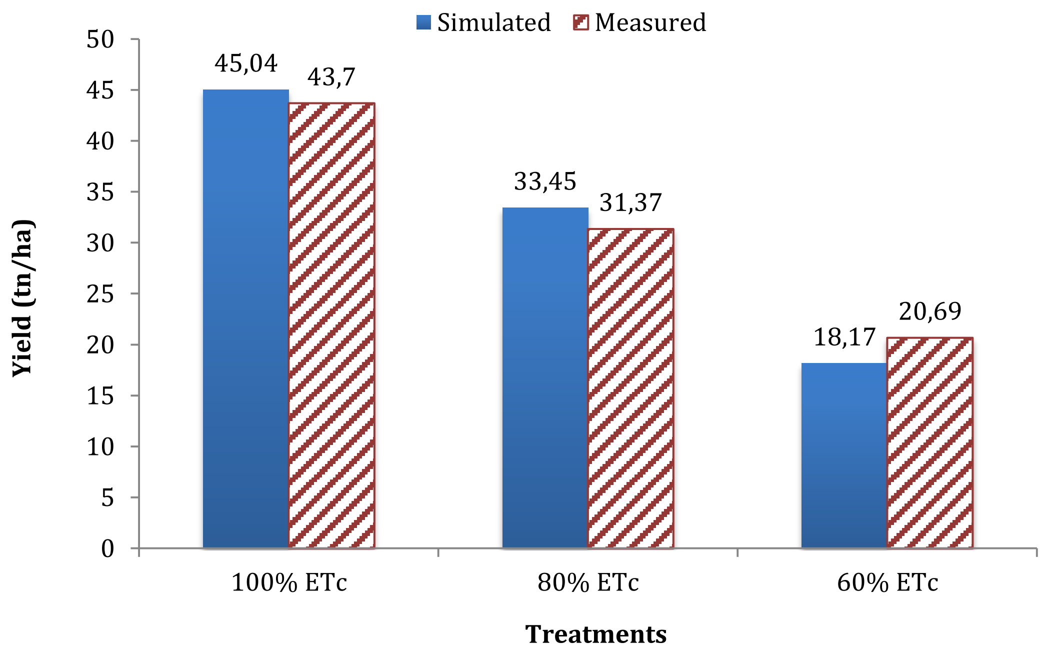

Figure 3. Comparison between simulated and measured industrial tomato yields under different irrigation treatments (100% ET_c, 80% ET_c and 60% ET_c).

The irrigation was carried out by using the automatic weather station, after the humidity was exhausted, as shown in Figure 4 indicatively for treatment of 100% ET_c. The SALTMED model during its implementation has the capability to graphically visualize the soil moisture profile at different distances from the emitter to a daily step.

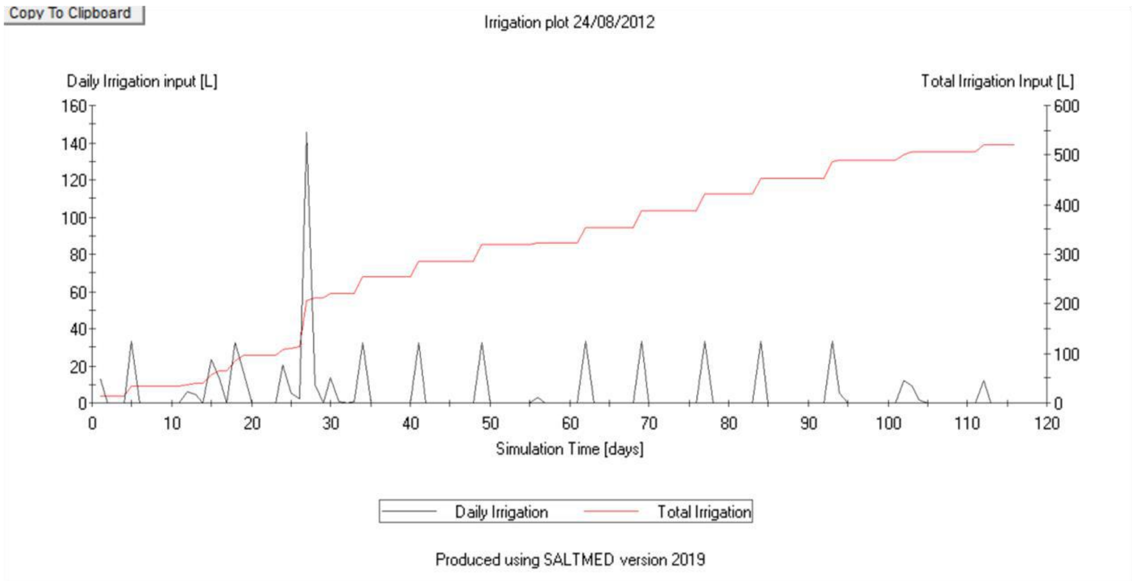

Figure 4. Volume of irrigation water added daily and in total for treatment 100% ET_c.

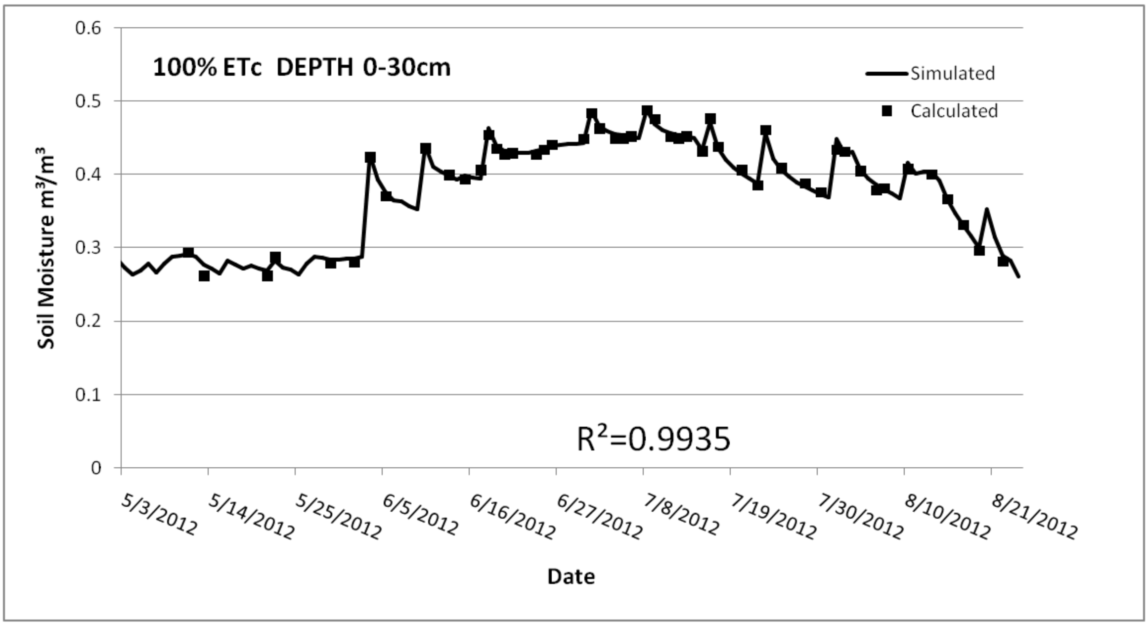
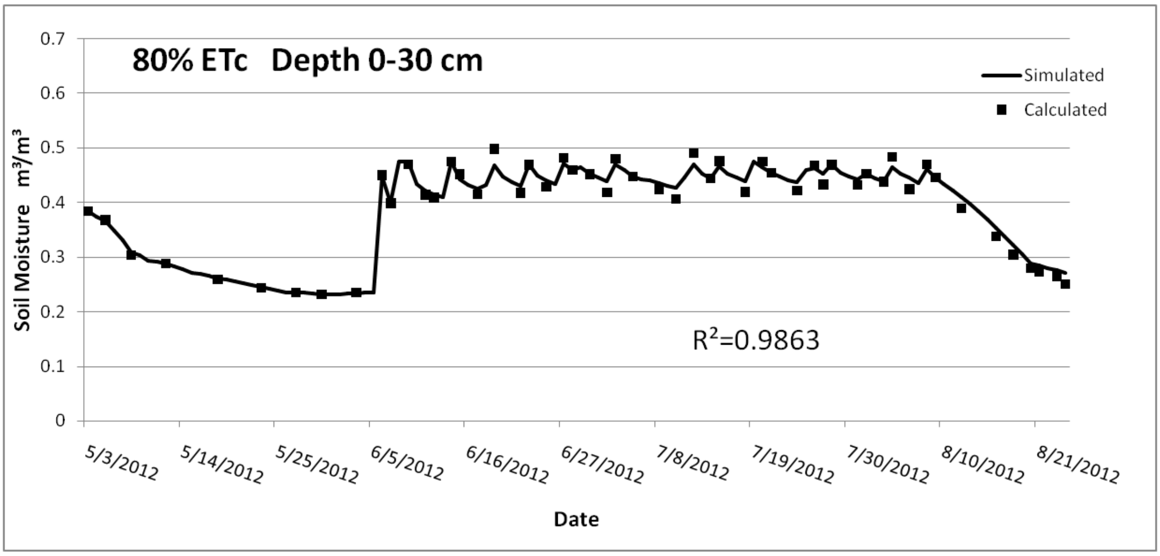
Figure 5 graphically represents the soil moisture at the location of the dripper at the depth between 0 cm and 30 cm with the measured and simulated values of soil moisture before and after irrigation with a very satisfactory approach. The model has shown a good fit of the simulated soil moisture when compared with the observed values.





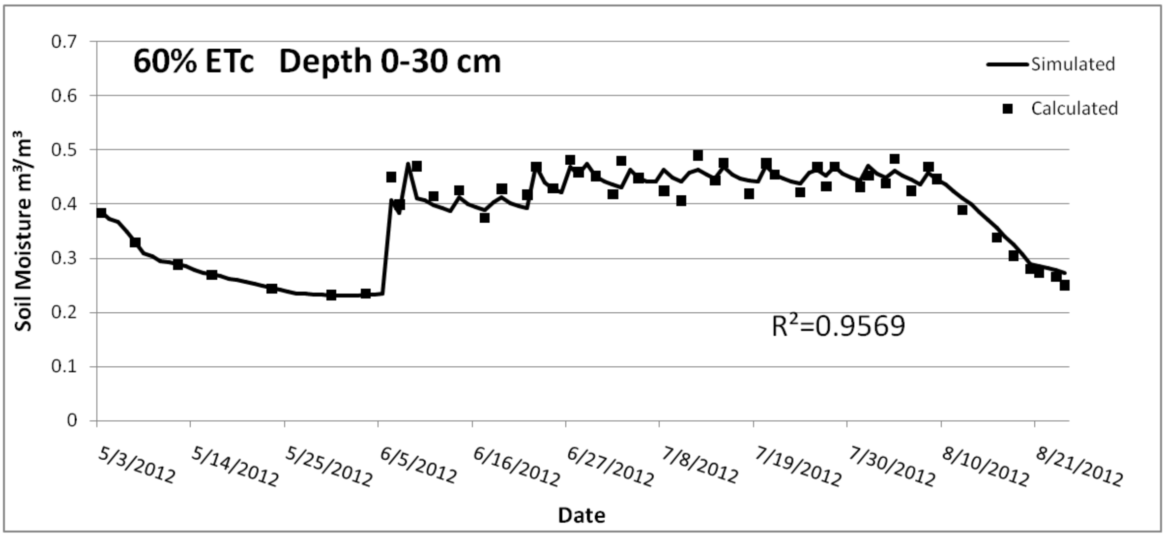


Figure 5. Graphic representation of measured and simulated soil moisture for industrial tomato within the top 30 cm depths, for the different treatments (100% ET_c, 80% ET_c and 60% ET_c).

Conclusions

In terms of model simulations, the model showed a strong relationship between the measured and simulated soil moisture and industrial tomato yield in a drip irrigation system. The mathematical model SALTMED adequately described the effect of the irrigation on the soil water balance, which makes it an effective tool in the irrigation water management practice.
A next paper will present the model's results using data from crops irrigated with saline water and different irrigation systems.

Abstract

Circular economy is aimed to create a *zero-waste* system by the reduction of wastes and their exploitation by turning them into by-products to be used as inputs for new production processes. In this perspective, packaging materials (glass and aluminium) were used to synthetize zeolitic materials to be evaluated for oenological application. A potassium (Zeo-K) and a sodium (Zeo-Na) zeolitic material (Zeo-K and Zeo-Na) were obtained, containing 16% and 30% of crystalline materials respectively. Both materials were then tested as oenological adjuvants, evaluating their ability to remove riboflavin from wines. Riboflavin is responsible of a photoxidation process leading to the onset of the light-struck taste in wines. Preliminary experiments were performed using a model wine solution, enriched with 300 μg L^{-1} of riboflavin. Each zeolite was added to the riboflavin-enriched solution at the concentrations of 1 g L^{-1} (Zeo-K1, Zeo-Na1) and 10 g L^{-1} (Zeo-K10, Zeo-Na10). For comparison, two bentonites were also tested at the concentration of 1 g L^{-1}. A control without either zeolites or bentonites was also run. The obtained results showed that riboflavin concentration remained unvaried in the control, whereas it decreased from 4% (Zeo-K1) to 37% (Zeo-Na10) in the treatments. Both zeolitic materials appeared less efficient than bentonites at the same concentration. Nevertheless, synthesizing zeolites with higher crystallinity is likely to lead to materials with higher efficiency, almost comparable to bentonites. Efforts are being undertaken to produce more effective zeolites from waste materials for oenological applications and to evaluate possible secondary effects on wine properties.

Keywords: *Circular economy, packaging materials, zeolites, wine, riboflavin, light-struck taste*

Introduction

Circular economy is aimed to turn goods that are at the end of their service life into resources for others, closing loops in industrial ecosystems and minimizing waste (Stahel, 2016). It is ultimately linked to resource cycling and to the 'waste-as-food concept', wherein unwanted outputs of one industrial process are used as raw materials in another industrial process (Murray, Skene, & Haynes, 2017). Business motivations for shifting from a linear to a circular economy are manifold. Economic advantages, namely cost reduction, new revenue sources and employment creation, have been identified and quantified for whole sectors or regions (Stewart, Niero, Murdock, & Olsen, 2018). Throughput materials, in particular, become end-of-life waste within a year, and the largest part of this fraction is potentially available for recycling after use (Haas, Krausmann, Wiedenhofer, & Heinz, 2015). Among these, food packaging can be a relevant source of raw materials for other products. Metal cans and glass bottles/jars, composing 5.8 and 0.6 % of municipal solid wastes (Consonni & Viganò, 2008) can provide, therefore, aluminium and silica as raw materials.
Aluminium and silica are also at the basis of zeolites' composition. Zeolites are tectosilicates characterized by high cation exchange capacity and a complex system of micropores and channels. Several synthesis processes have been developed in the last decades, in order to

produce zeolites with useful chemical and structural properties. Among the materials used for the synthesis of these aluminosilicates, glass and aluminium derived from food and drink packaging recycling have been recently proposed (Terzano, D'Alessandro, Spagnuolo, Romagnoli, & Medici, 2015). Thanks to their high sorption capacity, they are used in a number of industrial applications and also in the agri-food sector, especially after their classification as 'non-toxic' by International Agency for Research on Cancer (IARC) and 'safe for human consumption' by the Food and Drug Administration (FDA). Their applications range from storage pest management to food additives (Eroglu, Emekci, & Athanassiou, 2017). Some researchers proposed natural zeolites as oenological adjuvants, for protein/tartaric stability (Mercurio et al., 2010), phenolic off-odor removal (Lisanti, Gambuti, Genovese, Piombino, & Moio, 2017), prevention of light-struck taste due to riboflavin-induced photoxidation (Fracassetti et al., 2017).
The objective of the present work is to evaluate the potential of two synthetic zeolitic materials, obtained by an alkaline hydrothermal treatment of glass and aluminum recovered from drink and food packaging, for the removal of the photosensitizer riboflavin in a model wine system.

Material and Methods

White glass from drink bottles and food jars, and aluminum from cans of commercial soft drinks were used to synthesize a potassium zeolitic material (Zeo-K) and a sodium zeolitic material (Zeo-Na). Both starting materials were characterized for the chemical composition by wavelength dispersive X-ray fluorescence spectrometer (WD-XRF; Supermini 200, Rigaku Corporation, Tokyo, Japan). The zeolite synthesis was carried out according to the procedures reported by Terzano et al. (2015). Briefly, Zeo-K was obtained adding 1.6 L of a 5M KOH solution to 10 g of aluminum pieces in HDPE vessels, which were stored for 24 h at 25°C. Then, the aluminum solution was filtered with Whatman 1 and 160 g of glass fragments (Ø<2mm) were added to the filtrate. The suspension was stirred for 2 h and finally stored at 90°C for 7 days. The synthesis of Zeo-Na required the use of a 2.5M NaOH solution instead of KOH solution, and a crystallization temperature of 60°C instead of 90°C. In both cases, after the incubation time, the samples were cooled to room temperature and centrifuged at 5500 rpm for 15 min. The pellet obtained was washed three times with deionized water, then dried at 105°C for 24 h, and sieved at 500 μm. The materials obtained were analysed by X-ray powder diffraction (Miniflex II X-ray diffractometer, Rigaku Corporation, Tokyo, Japan) to assess their mineralogical composition.
The ability of the two zeolitic materials in reducing the concentration of riboflavin was preliminary assessed in a model wine solution, prepared with 5 g L^{-1} tartaric acid, 12% ethanol (v/v) and corrected for pH at 3.2 with NaOH. Riboflavin was added at the concentration of 300 μg L^{-1} in the model solution. Each zeolite was added to the riboflavin-enriched solution at the concentrations of 1 g L^{-1} (Zeo-K1, Zeo-Na1) and 10 g L^{-1} (Zeo-K10, Zeo-Na10). For comparison, two commercial bentonites (Bent1, Bent2) were also tested at the concentrations of 1 g L^{-1} for the capacity in removing riboflavin. A control without either zeolites or bentonites was also run. All the samples were stirred in the dark for 24 h at 25°C, then they were filtered at 0.45 μm and analysed by HPLC. All the treatments were replicated three times.
Riboflavin was detected using an Agilent 1200 Series HPLC-DAD system (Agilent Technologies, Santa Clara, CA, USA) consisting of a G1311B quaternary pump, G1329B auto-sampler injector (30 μL sample loop), G1316A Thermostatted Column Compartment, G1315D Photo diode array detector, in a series configuration. The stationary phase was a RP C18 Acclaim^{TM} 120 column (3 μm, 150 × 3 mm) (Thermo Fisher, Waltham, MA, USA) at a column temperature of 25 °C. The mobile phases were (A) 90% 50 mmol citrate buffer at pH

2.5 and 10% methanol (v/v) and (B) 10% 50 mmol citrate buffer at pH 2.5 and 90% methanol (v/v). The elution program was: from 100% A to 30% (0-8 min), from 30% A to 100% (1 min), 100% A (9-15 min); flow rate of 0.6 mL min^{-1}. PDA detector was monitored at 440 nm. Quantitative analysis was performed according to the external standard method on the basis of calibration curve obtained by injection of solutions at known concentrations in the range of 0.01-3 mg/L (R^2=0.9998). Results were expressed as mg L^{-1}.

Results and Discussion

Both glass and aluminium used for the zeolite synthesis did not contain any potentially toxic element, as revealed by the WD-XRF analysis. The XRPD patterns of the two zeolitic materials are shown in Fig. 1. The Zeo-K synthesis produced the formation of 16% edingtonite, whereas the Zeo-Na synthesis caused the formation of 30% zeolite-A. The broad hump between 20 and 30° 2θ in XRPD patterns suggested the presence of a considerable amount of amorphous phases, consisting of cryptocrystalline and poorly ordered fractions. Both zeolitic materials were characterized by a high cation exchange capacity (260 and 390 $cmol_+$ kg^{-1} for Zeo-K and Zeo-Na, respectively). The other chemical and structural properties of zeolites synthetized are reported in Terzano et al. (Terzano et al., 2015).

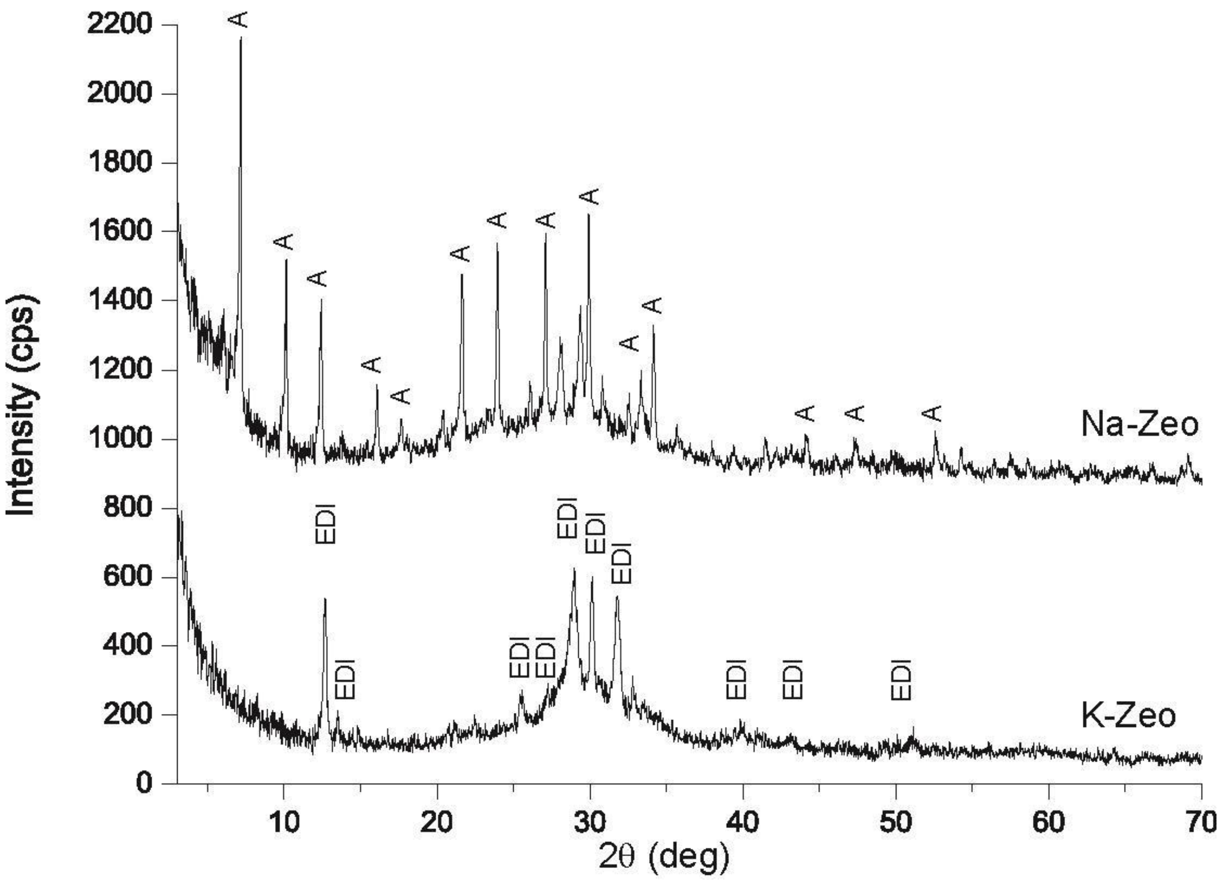

Fig.1 Diffraction patterns of Zeo-Na and Zeo-K, and main reflections of zeolites detected in the two samples (A: zeolite-A; EDI: edingtonite).

The model wine system was spiked with an amount of 300 μg L^{-1}, that is in the upper end of the concentration range of riboflavin found in wine, as reported in literature (Fracassetti et al., 2017). Two different commercial bentonites, commonly used as wine fining agents, were used to compare the ability of the zeolitic materials to remove riboflavin.

The HPLC analyses revealed that the riboflavin concentration remained unchanged in the control and in the treatment Zeo-K1, whereas it significantly decreased in all the other treatments (Figure 2). Bentonites reduced riboflavin amounts by 14.7% and 20.9% Fracassetti et al. (2017) previously obtained better performances from commercial bentonites (1 g L^{-1}), removing about 40% of riboflavin in a model wine system containing higher amounts of photosensitizer (350 μg L^{-1}). The reduction due to Zeo-Na1 was only 8.3%. Nevertheless, it should be considered that commercial bentonites for oenological use have a legal content of active crystalline aluminosilicates (montmorillonite) of at least 80% (90-95 % in the tested bentonites, according to the technical sheets). The lower removal ability of both zeolitic materials might be ascribed, therefore, to their low content in zeolites. In these preliminary tests on the synthetized zeolitic materials, their addition in higher amounts was also evaluated. Zeo-Na10 and Zeo-K10 resulted the most effective treatments, causing 37% and 26% of removal, respectively. In all treatments, however, the residual amount of riboflavin was higher the target that would avoid the appearance of light-struck taste in wines (100 μg L^{-1}).

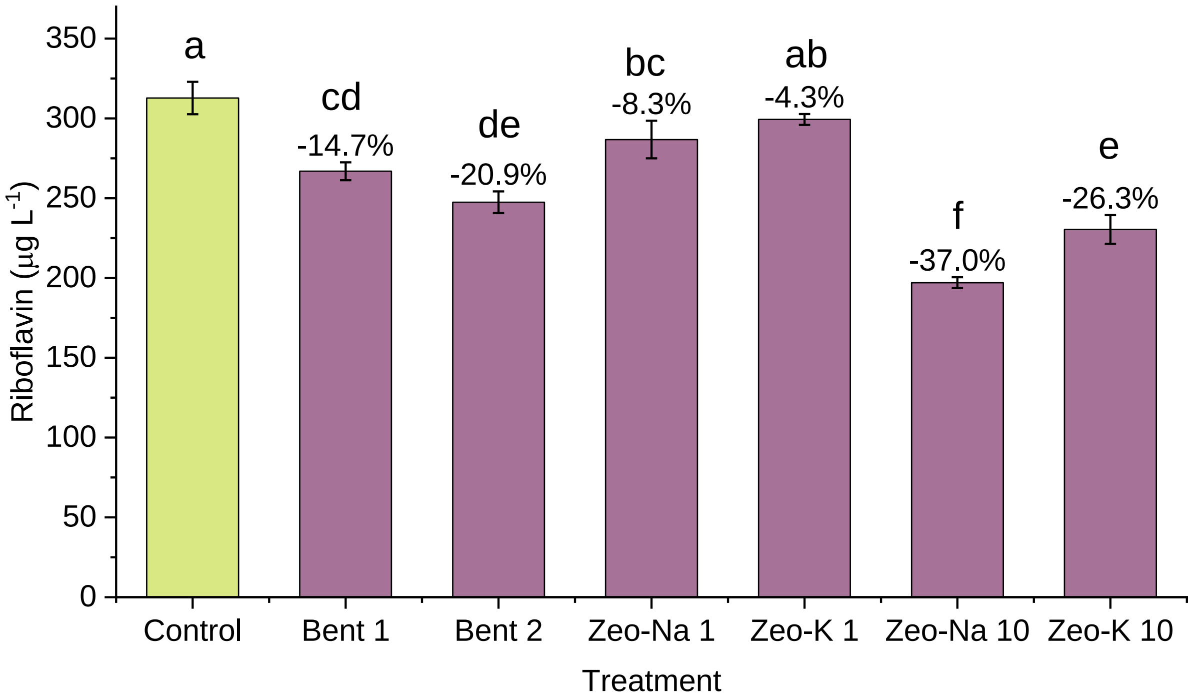

Fig.2 Amounts detected by HPLC-DAD analysis in the control model wine system and in the samples treated with bentonites and zeolitic materials. For treatment codes see Materials and methods. Means ± standard deviation of fhree independent replicates. Different letters mean a significant difference at $p < 0.05$.

However, the ability of zeolitic materials obtained from packaging materials was proven. Further research is needed to obtain more effective zeolitic materials, by either increasing their purity or tailoring their structural properties. Moreover, secondary effects on wine composition and sensory properties should be evaluated. In fact, in case of bentonites, the tested amounts (1 g L^{-1}) could result detrimental for wine sensory properties (Fracassetti et al., 2017). As regards zeolites, tests on natural zeolites applied to wine have been carried out at quite higher concentrations (up to 8 g L^{-1}) (Mercurio et al., 2010) and no data is available at this moment on the highest tolerable amounts that could be used without affecting wine properties.

Conclusions

Two zeolitic materials obtained from food packaging were tested for the first time as possible oenological adjuvants, with the aim to reduce the levels of the photosensitizer riboflavin. Both materials resulted able to partially remove riboflavin (up to 37% less than control), though with lower efficiency compared to commercial bentonites. Further research will be focused on improving their purity and efficiency, and to evaluate possible secondary effects on wine properties.

THE ECOLOGICAL FORMULATION OF A PESTICIDE MANUFACTURED BY JSC SCHELKOVO AGROHIM (RUSSIA) ON THE EXAMPLE OF THE HERBICIDE ZONTRAN CSC

Salis KARAKOTOV, Elena ZHELTOVA, Sergey KLISHIN*

JSC Schelkovo Agrohim, Moscow Region, Schelkovo, Russian Federation

Abstract

The results of studying the effectiveness of the herbicide Zontran CSC, containing the active substance metribuzin 250 g/l in a preparative form (formulation) named Colloidal Solution Concentrate (CSC) are presented. Experiments were carried out for two years in 2011–2012 on soybean crops with mixed type of weeds: annual dicotyledonous and annual grasses. The biological effectiveness of Zontran CSC was compared with a product containing metribuzin 700 g/kg in a formulation Wettable Powder (WP). It was established that the pre-emergence application of Zontran CSC on soybean crops at a dose rate of 1.2 l/ha was comparable to the biological effect of the product, consisting of metribuzin at 2.3 times more, but in the WP formulation. It was observed that Zontran CSC in comparison with the product containing a higher amount of metribuzin, but in the WP formulation, was at the level, and in some cases exceeded the biological effectiveness of this product. Thus, the formulation of the colloidal solution concentrate allowed, without loss of biological effectiveness and with obtaining reliable yield increases, to reduce the amount of metribuzin per unit of cultivated area, which makes the use of pesticide environmentally friendly, since minimizes its release into the environment.

Keywords: *Herbicides, metribuzin, colloidal solution concentrate, formulation, soybean.*

Introduction

Intensive application of the mineral fertilizers and pesticides are the cause to the yearly entry into the biosphere of various chemicals. In this regard, the problem of environmental protection, especially when using pesticides, is important (Ganiev and Nedorezkov, 2006). The use of pesticides ensures to save crop yield by controlling the number of harmful objects. However, applying pesticides during or before the vegetation periods leads to the fact that chemicals that can adversely affect the soil biota and terrestrial organisms are released into the environment and accumulated in the form of residues in agricultural products. Therefore, reducing the pesticide accumulation on nature is actual and significant.

Biological efficacy of the products depends on the active substances in their composition, as well as the amount of active ingredient that interacts with the harmful objects, which is determined by the dose rate of the pesticide. Preparative form of pesticide (Formulation) is the composition of the active substance of the pesticide and auxiliary substances, ensuring the delivery of the active substance to the target object.

The different biological efficacy is achieved with the same active ingredient and its equal amount but depending on the type of formulation. The dose rate decreasing of active ingredients may lead to a decrease in biological effectiveness.

JSC Schelkovo Agrohim set a goal to create products that would have a biological efficiency comparable to the level of traditionally used pesticides, but contained a smaller amount of the same active ingredient per unit of cultivated area in order to minimize the pesticide environmental accumulation. This effect was supposed to be obtained by means of a new formulation, which is a special case of the emulsion concentrate (EC) - the colloidal solution concentrate (CSC). CSC is an EC which, when preparing the working solution, forms a colloidal system. A colloid system is a system in which discrete particles, droplets or bubbles of a dispersed phase, having a size in at least one dimension from 1 to 100 nm, are distributed in another phase, usually continuous, different from the first in composition or aggregative state and called dispersion phase. The popularity of colloidal systems lies in their unique properties that are transmitted to colloid-based products: the system is homogeneous, there is no sediment (the product has a transparent colour), a high coverage ratio, wetting is ensured, which cause to a significant increase in the degree of absorption of active substances, and as a result, optimization of biological activity.

A whole line of the products of CSC formulation was created, one of them is the herbicide Zontran CSC containing 250 g/l of metribuzin.

Metribuzin is included as an active ingredient in many pesticides. It is used pre- and post-emergence to control weeds on following crops: potatoes, wheat, tomatoes, carrots, soybeans, and sugarcane. The mechanism of action is based on the inhibition of the photosystem II (Metabolic Pathways of Agrochemicals: Herbicides and plant growth regulators, 1998).

The objective of this research was to study the biological effectiveness of the herbicide Zontran CSC and compare it with its analogue (hereinafter referred to as Analog) containing 700 g/kg of metribuzin in the formulation Wettable Powder (WP).

Material and Methods

Biological trials were carried out for two years in 2011–2012 in three regions of the Russian Federation on the soybean varieties Annushka, Bara, Svetlaya. The Zontran CSC was applied pre-emergence, on vegetative weeds with dose rates of 0.6, 0.8 and 1.2 l/ha, which corresponds respectively to the application of metribuzin 150, 200 and 300 g/ha consequently. At the application time, weeds were in the phase of cotyledons - two leaves.

The biological efficiency of Zontran CSC was compared with the Analog containing 700 g/kg metribuzin, formulation Wettable Powder (WP), in dose rates of 0.5 and 1.0 kg/ha, which corresponds to 350 and 700 g of metribuzin on ha respectively. The trials were provided in accordance with the "Guidelines for registration testing of herbicides in agriculture" (Dolzhenko V.I., 2013) under conditions of small plots of 0.25 m^2 in the mixed type of weediness. The names of weed plant species were given in accordance with the work of P.F. Mayevsky "Flora of the middle zone of the European part of Russia"(Mayevsky P.F., 2014).

The study was conducted by an independent source namely All-Russian Institute for Plant Protection (VIZR), the results of this research Zontran CSC received an extension of official registration of pesticides in the Russian Federation for soybeans.

The determination of the particle size of the Zontran CSC was carried out on a Photocor Compact instrument using photon correlation spectroscopy. Particle size analysis of the Analog (WP) has been done on a Fritsch Analysette 22 MicroTec Plus instrument by laser diffraction. The surface tension of each of the products were determined by the method of ring detachment on a Kruss K6 tensiometer.

Results and Discussion

In case of pre-emergence application of the Zontran CSC in soybean crops following weeds were effectively suppressed: *Stellaria media L.* (85%), *Amaranthus retroflexus L.* (94,6%), *Chenopodium album L.* (94%), *Echinochloa crus-galli L.* (81%) *Thlaspi arvense* (82%) (Fig. 1).

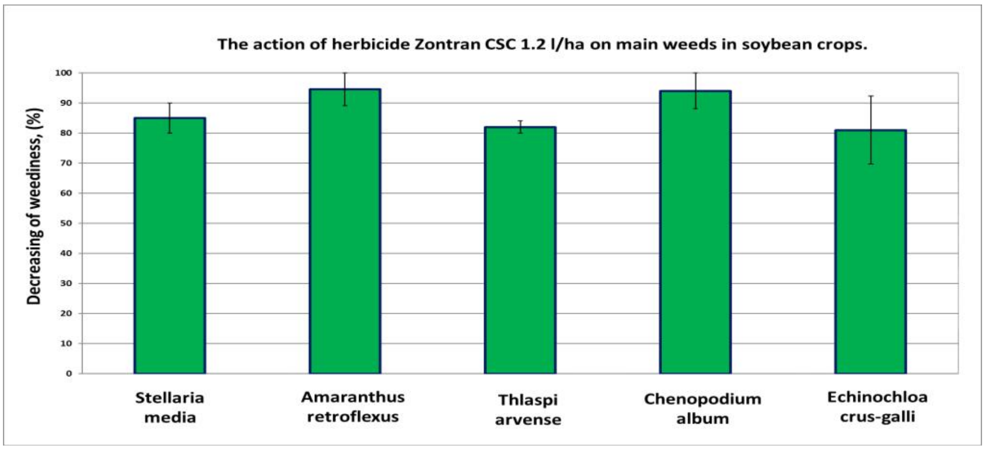

Fig. 1. Efficacy of pre-emergence application of the Zontran CSC herbicide on the main types of weeds in soybean crops.

The Zontran CSC effectiveness of action on annual dicotyledonous weeds in dose rates of 0.6 and 0.8 g/l (metribuzin 150 and 200 g/ha respectively) was comparable with the efficiency of the Analog in the dose rate of 0.5 kg/ha (metribuzin 350 g/ha), and at a dose rate of 1.2 l/ha (metribuzin 300 g/ha), the effect of Zontran CSC approaches to the Analog effect in a dose rate of 1 kg/ha (metribuzin 700 g/ha) (Fig. 2). By the effectiveness of the action on annual grass weeds, the use of the herbicide Zontran CSC in dose rates of 0.8 and 1.2 l/ha was comparable to the efficiency of the Analog in the dose rate of 0.5 kg/ha (metribuzin 350 g/ha) and 1 kg/ha (metribuzin 700 g/ha), in the dose rate of 0.6 l/ha the effectiveness was lower. (Fig. 3). In variants with the Zontran CSC application of 0.8 and 1.2 l/ha the weight loss of annual dicotyledonous weeds was 98-100%, the weight of annual grasses species - 94-100%, which corresponded to efficiency of Analog in the dose rate of 1 kg/ha. Weight loss of weeds with the use Zontran CSC of 0.6 l/ha was at the level of Analog efficiency of 0.5 kg/ha, which was 89-98% for annual dicotyledonous weeds and 88-93% for grasses.
Elimination of competition with weeds in the initial period of crop vegetation allowed to save from 26.1 to 58.7 % of the soybeans harvest an medium weediness of crops (annual dicotyledonous weeds 48-49 ind./m^2 (194 g/m^2), annual grasses 60-63 ind./m^2 (360 g/m^2)), and from 28.2 to 32.9 % with high weediness (annual dicotyledonous weeds 242-256 ind./m^2 (580 g/m^2), annual grasses 151-154 ind./m^2 (315 g/m^2)). (Table. 1)

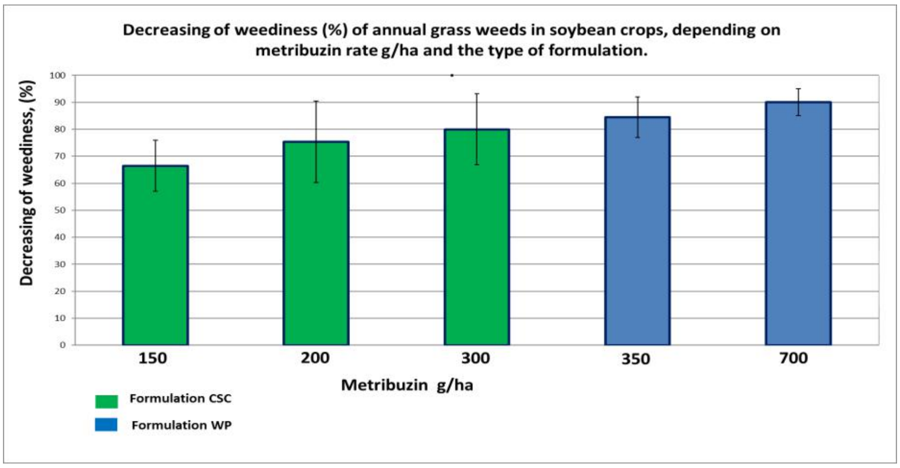

Fig. 2 The biological effectiveness comparison of Zontran CSC and another metribuzin-containing product Analog WP on annual dicotyledonous weeds in soybean crops, depending on the application rate of metribuzin g/ha and the type of formulation

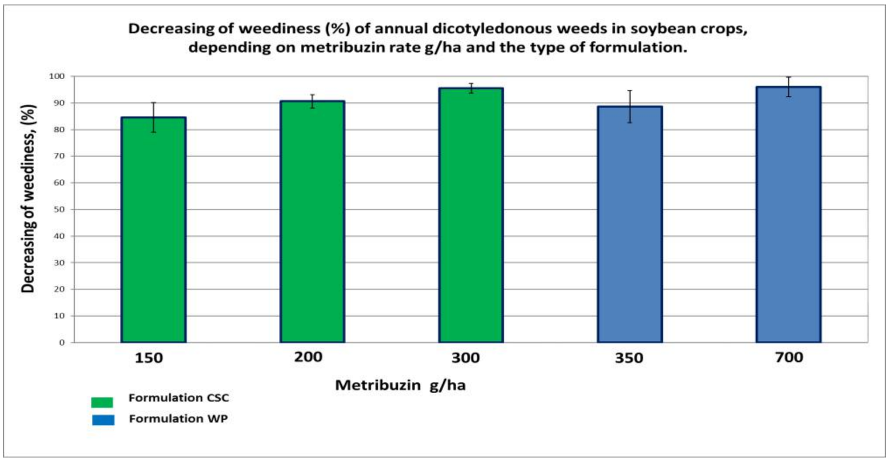

Fig. 3 The biological effectiveness comparison of Zontran CSC and another metribuzin-containing product AnalogWP on annual grass weeds in soybean crops, depending on the application rate of metribuzin g/ha and the type of formulation.

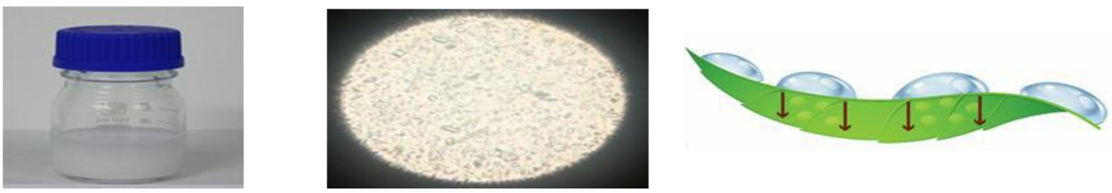
Table 1. The influence of herbicides of different formulations on the saved yield of the soybean crops (variety Annushka) with a high and medium degrees of weediness

Weediness	Yield in control hundredweight /ha	Saved yield (%) when applied Zontran CSC 1,2 l/ha	Saved yield (%) when applied Analog WP 1 l/ha
High	4,6	26,1 - 58,7	32,6 - 58,7
Medium	14,9	28,2 -32,2	30,2 - 35,6

By the photon correlation spectroscopy method, the particle size of Zontran CSC was determined as 1.327 nm. A small size of particles carrying the active substance leads to suggest that the "targeting" of metribuzin delivery of Zontran CSC will be higher than the metribuzin from Analog formulation WP with a particle size of 5 mkm. The stability of an emulsion depends on many factors, for example, surface tension, viscosity of the dispersion medium, temperature, particle dispersion, etc. But of all the above, the main factor of emulsion stability is the size of the emulsified particles, that is, its dispersion. When the size of the droplets decreases, the effect of gravitational forces decreases and the forces that keep them in a stably suspended state begin to prevail (Kireev,1978).

Colloidal Solution Concentrate (CSC)

A **B** **C**



A **B** **C**

Wettable Powder (WP).

Fig. 4 Comparison of two formulations: CSC and WP.

A- is the appearance of the working solution,

B- is a view of the formulation homogeneity by the light microscope (1600x),

C- is the intended effect on the surface of the plant leaf.

It was proved that the surface tension of a droplet containing the active substance in the CSC form will be less (37 mNm) than the WP formulation (46 mNm), which means that the droplet spreading over the surface and holding it on the plant leaf for CSC will be higher than the WP (Fig. 4) Due to the above factors, the efficiency of using the active substance in the CSC formulation will be higher than in the WP formulation, which allow to reduce the dose rate of the active ingredient per unit of cultivated area and, using colloidal formulation, achieve a similar or increased biological efficiency compared to standard forms.

Conclusions

The effect of application of Zontran CSC on soybean crops at a dose rate of 1.2 l/ha was comparable with product contenting at 2.3 times more metribuzin but in WP formulation, while the application rate of metribuzin per 1 ha is 300 g/ha and 700 g/ha, respectively. Thus, the CSC formulation allows reducing the amount of the active substance per unit of cultivated area without loss of biological efficiency and with obtaining reliable yield increases. The product Zontran CSC was included in the State Catalog of Pesticides and Agrochemicals permitted for use on the territory of the Russian Federation (State catalog of pesticides and agrochemicals, 2018) in soybean crops with a dose rate of 0.6-1.2 l/ha.

THE PLACE OF GREEN PRODUCTION IN ENVIRONMENTAL PROTECTION AND NATURAL RESOURCE MANAGEMENT

Sertaç ARI*, Durmuş Ali CEYLAN

Abstract
The rapid increase of the population every day, it also increases production with consumption. Recycling and green production concepts gained importance as a result of the negative consequences of the wastes released to the environment during the production in the soil, water and air. With the implementation of these concepts, waste from the environment has been reduced with the recycling of waste, on the other hand, natural resources are preserved. at this point, there is a social responsibility for both producers and consumers. Reducing the damage to the environment as much as possible in production, the use of renewable resources in production rather than natural resources is a major task for producers; consumers also prefer to use environmentally friendly green products while consuming. This choice forces manufacturers to produce green. In this study, studies on green production related to environmental protection and non-consumption of natural resources were evaluated. In addition, the contribution of the sample companies that match the green production to the environment, natural resources and the country's economy has been examined.

Keywords: *Green Production, Environmental Protection, Eco-Friendly Product, Natural Resources.*

Introduction
In order to survive, people interacted with the environment continuously and made it easier for them to use natural resources. However, the rapid increase of the population, the construction of giant factories with the industrial revolution, global warming, rapid industrialization with mechanization, harmful wastes, unconscious resource use have caused air, water and soil pollution. All of these have caused both depletion of resources and deterioration of ecological balance. As a result, consumers have realized that natural resources are rapidly depleting and that natural life is now moving towards uninhabitable points and that act within the framework of this responsibility. These consumers, who are considered as green consumers, are more sensitive about waste of resources, environmental pollution and recycling of products (Haden et al., 2009; Kükrer, 2012).
Rapidly increasing environmental problems are no longer an individual problem and have become a concern for the whole society. Within the framework of these problems, it is clearly seen that the sensitivity of consumers towards the environment has increased and it is necessary to reflect this sensitivity to the behaviors of people. However, although the majority of consumers are worried that natural resources are rapidly depleting and nature is being destroyed, it is seen that this is not only a matter of concern, but does not reflect how they should be treated in the process of buying, consuming and following the use (Hussein & Cankül, 2010). In the face of such a problem, it is important to raise awareness of consumers against environmental problems and to ensure that less harmful products are consumed.
The use of the world's resources as if they were never exhausted, and environmental problems that threaten people's lives and ecosystems have pushed states to work to protect and sustain the natural environment. In fact, it is necessary to develop international cooperation and environmental policies since the countries understand that the problem cannot be solved alone and improvement works will not be enough. In line with these developments, the pressures of

production and service companies to pay more attention to the environmental-based results of the products and services they produce and the processes they apply are increasing exponentially (Kleindorfer et al., 2005).

Green Product Concept

Product; color, brand, packaging, design, after-sales services are the aggregate of concrete and abstract qualities including the image of the seller (Altunışık et al., 2016).

Green product; Although it is expressed as more environmentally friendly, the recovery or disposal of wastes can be defined as the product that uses the energy sources at the lowest level, which helps to protect the natural environment (Ottman et al., 2006).

In order to qualify a product as a green product, there are some features that it must carry. These features are briefly (Moisander, 2007; Elkington et al., 1990);

- ✓ Manufacturing, consumption and after-consumption processes should be in a way that will not harm the environment,
- ✓ Not disproportionately consume energy and other resources in production, consumption and storage,
- ✓ Do not contain harmful materials that do not harm the environment or species, do not cause environmental pollution, and contain reusable packages,
- ✓ It must be of a quality that will not harm human and animal health,
- ✓ Should not cause unnecessary waste / waste in nature due to excess packaging or short-term use,
- ✓ Should not be used unnecessarily and should not torture animals,
- ✓ It should not harm the environment during storage.

When the previous researches are examined, it is understood that 70% of the damage caused by a product occurs in the production and design stages of the product (Polonsky & Rosenberg, 2001).

Therefore, the green product, will not pollute the environment, all or a large majority can be re-nature, packaging, brand, design, after-sales services, water and energy saving, taking into account a number of features such as the use of raw materials to production and consumption so that the process should be designed to cause minimal damage to nature (Mahlangu, 2014).

Green Production Approach

Green production includes production processes that use inputs with little impact on the environment, do not generate waste or generate very little waste and do not generate environmental pollution. Atlas and Florida examined green production alternatives under five headings (Atlas & Florida, 1999): change in production inputs, internal use of waste, change in product, better management and change in production processes.

Green production of enterprises, that is, the management level to act with a green management approach, will provide serious advantages in terms of sustainability by focusing on continuous improvement of the enterprise (Kautto, 2006).

Economic and Environmental Effects of Green Production Practices

In 2016, 18 projects realized within the scope of energy efficiency activities at 4 refineries within Tüpraş saved 30,186 TJ of energy and 92,675 tons of CO_2 emissions. The amount of greenhouse gas emissions reduction in the last 10 years has reached 2.1 million tons.

In 2016, Tüpraş continued its water recovery activities. Thanks to these efforts, 20 million m^3 of water was recovered.

In 2016, Tüpraş recovered 67% of 41,506 tons of waste, of which 30,872 tons were hazardous and 10,534 tons were non-hazardous. Non-recyclable wastes were disposed of by licensed companies with the norms and methods specified in the legal regulations.
Within the scope of afforestation activities, Tüpraș planted 600 saplings in 2016 and prevented emissions to 200 tons of CO_2 (Tüpraş).

PINAR

Thanks to the optimization efforts in its production processes, Pınar Süt has created less waste water and reduced water consumption by 9%. It also reduced the amount of paper used in cheese and yogurt cartons.
Pınar Et reduced its total carbon emissions by 11% compared to 2010. Within the scope of box improvement works, it has reduced the amount of paper used per box by 30% in some of its products. The carbon emissions from shipping parcels were also reduced. With the change of design in the boxes of the open-end sliced products; It has used 104 tons less paper, resulting in a 6.4% reduction in the use of paper packaging. Annual carbon emissions from these products decreased by 87%.
Pınar AŞ planted 1 tree for the employee who brought 10 batteries with his "voluntary employee project". A total of 1000 trees were planted. Thanks to the non-disposable batteries, 6,000 m2 of soil and 600 million liters of water are prevented from being polluted.
Pınar Su has reduced its carbon emissions by 13% over the previous year (Pınar, 2019).

opet

Opet prevented 104 tons of CO_2 greenhouse gas emissions in 2014 and 106 tons of CO_2 in 2015 as a result of its energy efficiency efforts.
With the establishment of the solar power plant at the Mersin Terminal, it supplies 8% of its annual energy need from a renewable energy source.
In 2015, 80% of hazardous wastes generated at its terminals and 85% of non-hazardous wastes were recycled.
The volume of water recycled and reused in 2015 was 84,571 m3 with a recovery rate of 57% (Opet, 2019).

Ford

Ford Otosan attaches importance to providing the energy they use in production from renewable energy sources. With the installation of wind turbines and solar panels, it produced 89 Gj of energy in 2017. This ratio increased to 2,368 Gj in 2018. Thanks to the energy efficiency projects it has implemented, it has saved 79,869 Gj of energy and prevented 4,860,6 tons of CO_2 emissions. With the projects developed within the scope of water management, 1.17 million m3 of water was consumed in 2018 and 25% of this was recovered. In 2019, they redesigned their water management projects in order to recover 75-80% of the water used. With the optimization of the production process, the consumption of the chemicals used was reduced and productivity was achieved. Accordingly, they reduced solvent consumption per vehicle by 18%. In 2018, a total of 95,364 tons of waste was recycled (Ford, 2019).

Unilever explains that by 2025, 100% of the plastic packaging used in its products will be recyclable. With its new factories, design and production systems, the company is implementing a 50% reduction in carbon emissions and water consumption compared to similar production centers. At the end of 2017, 56% of agricultural raw materials were obtained from sustainable sources (Unilever, 2019).

In 2018, Tofaş achieved 79,935 GJ of energy savings and 5,387 tons of CO_2 greenhouse gas emissions reduction through energy efficiency projects. The company has recovered 64,555,900 m3 of water used in vehicle production with its innovations. 100% of the packaging wastes are recycled and reused (Tofaş, 2019).

Thanks to effective water management practices, it saved approximately 199,862 m^3 of water in six countries. This figure replenishment rate reached 150% in Turkey. In other words, for each liter of water used in production, it replaces 1.5 liters of water. This equals approximately 4,271 million liters of water. As a result of the projects carried out by Coca Cola, the company achieved an improvement of 468 million kWh in energy consumption in its factories in 6 countries. This corresponds to a reduction in CO_2 emissions of approximately 78,711 tons. This figure corresponds to the amount of CO_2 absorbed by approximately 6.6 million trees a year. Total waste recycling plant in all of the Company 96.0% in Turkey, Jordan, 91.90%, 90.0% in Kazakhstan, 97.8% in Azerbaijan, Kyrgyzstan is 94.44% and 97.7% in Pakistan (Cci, 2019).

With its solar, water, wind and biogas fuel cell projects, Apple meets the power requirement of all its facilities with 100% renewable energy. Since 2011, the use of renewable energy has reduced CO_2 equivalent emissions of its worldwide operations by 54% and prevented

approximately 2.1 million metric tons of CO_2 equivalent emissions into the atmosphere. Even in 2017, the company reduced its CO_2 equivalent emissions by about 590,000 metric tons (Apple, 2019).

Starbuck saves energy and water by using environmentally friendly materials and systems that reduce carbon emissions through environmentally friendly stores. One of the notable campaigns of Starbucks is the project of transforming cardboard glasses into plastic cups. Significant water savings are achieved in the stores with the renewed water tank system. Energy saving bulbs are used to reduce energy requirements and carbon emissions. Used coffee grounds can be used as fertilizer to feed plants by offering them free of charge (Starbucks, 2019).

Turkey's first hybrid bus carrying the Hybrid Avenue feature uses the Siemens ELFA Hybrid Systems. These systems exhibit an environmental approach with lower carbon dioxide emissions and zero emissions. TEMSA Hybrid Avenue saves up to 25 percent in fuel consumption and carbon dioxide emissions compared to diesel buses (Capital, 2019).

Türk Telekom provides carbon savings through its efforts to use alternative energy sources such as solar energy and wind energy. In 2010, Türk Telekom became the first Turkish telecommunications company to report to the CDP (Carbon Disclosure Project). In 2016, carbon emissions decreased by 16% with efficiency and abatement projects compared to the previous year (Turktelekom, 2019).

The recycling rate of ARÇELİK A.Ş. products varies between 83.9% and 98%. Approximately 1650 trees were cut down by 85% and 60% reduction in the rate of wood used in the packaging of the products. Logistics "Environmentally Responsible Networks Network" approach is adopted. In this context, is made with approximately 70% of the sea's exports to Turkey, arrival ports after also preferred that is sensitive to the environment in all possible destinations railway and-borne transport. At the same time, low-emission vehicles are preferred in the vehicles used within the scope of Authorized Services and Consumer Services, and vehicles over the age of 5 are renewed and continuous emission improvement is provided. (Arcelikas, 2019).

The company has saved more than 1.8 billion liters of water and recycled more than 129 million liters of water so far by reusing the water used during production and switching to new finishing methods that require less water than traditional production processes (Levis, 2019).

Conclusions

The rapid depletion of natural resources, the state's sensitivity to the environment and consumer preferences for environmental products increase competition conditions day by day. Consumers have begun to demand products that are renewable, create less pollution, are safer for the ecosystem and are recyclable. At this point, the presence of consumers who behave more consciously than in the past provides an environment for producers to be environmentally friendly. Another point that needs to be considered here is that the conscious consumer group, who conducts research and questioning, wants to know how nature is protected not only from environmental certificates on products but from the production stage to the consumption stage. In other words, whether the factories where the products are produced does not harm the environment, whether the products are raw materials, packaging,

whether the energy used is environmentally friendly or even the transportation operations used during the delivery of the product to the final consumer affects the product preferences of the conscious consumers. Therefore, consumers' preference situations will make significant contributions to the planning of the enterprises for their environmentalist approaches, the structuring of production strategies, production structuring and marketing management.
Starting from this point of view, developing state strategies to raise awareness of consumers about green consumption and carrying out awareness-raising activities in particular to increase the environmental sensitivity of the young generation will encourage consumers to receive environmentally sensitive products and services from production to consumption. In this case, it will require producers to produce environmentally friendly products in order to survive.

Abstract

Produced Water (PW) is the major waste water stream of petroleum industry. This produced water, due to its unique chemical composition, supports many hydrocarbon-degrading microorganisms. The presence of high carbon content and low nitrogen content indicated that produced water was an ideal environment for many bacterial species that produce polyhydroxyalkanoates (PHA), an intracellular storage polymer. The main purpose of this study was to isolate bacterial strains that can produce large amounts of PHA on different carbon sources. While *Bacillus* sp. producing PHA used for Plant microbe interaction studies carried out with wheat crop.Produced water sample was collected from Potwar oil fields in sterilized bottles and stored at 4^{o}C. Sample was appropriately analyzed for many parameters including temperature, pH, odor, texture and color. Isolation of bacterial strains was performed according to serial dilution method. Isolated strains were screened for PHA production by using PHA detection media supplemented with Nile blue. Plant growth promotion experiment was done on PHA producing *Bacillus* sp. with wheat crop (*Triticum aestivum*).The use of glucose as sole carbon source resulted in highest production of PHA (43%), after 24 hours cultivation by *Bacillus sp.*(MH142143). It showed significant results in bioremediation of hydrocarbons. Maximum germination of 93% was observed in wheat seedlings when supplemented with*Bacillus sp.* with marked increase of 72.87cm in wheat seedling length in lab scale experiment. Results of this study helps in the elimination of hydrocarbon from produced water by *Bacillus sp.* and make it suitable for agriculture.

Key words: *Produce water, Bacillus, Triticum aestivum, polyhydroxyalkanoates, Plant microbe interaction.*

Introduction

The use of petroleum and petroleum base polymers has increased to an alarming degree. Polyhydroxyalkanoates (PHA) are biodegradable plastics that have the potential to replace these petroleum-based polymers.Polyhydroxyalkanoates (PHAs) are inclusion bodies, used as storage reserves by the cell. Most common PHAsare polyhydroxybutyrate (PHB) (Santhanam & Sasidharan, 2010), produced by *Pseudomonas*, *Bacillus*, *Alcaligenes*, *Rhodococcus*, *Agrobcterium*, *Comamonas*, *Hydrogenophaga*, *Ralstonia* etc. (Lee, Kang, & Choi, 1995). These bio-polyesters are biodegradable as well as biocompatible (Povolo et al., 2013).

The properties of PHAs are strongly dependent on their monomeric composition and structures. Poly (3-hydroxybutyrate-co-hydroxyvalerate) has lower crystallinity and melting point than poly (3-hydroxybutyrate). Whereas polyethylene has low tensile strength and malleability as compared to poly (4-hydroxybutyrate) (Povolo et al., 2013). Increase in poly (3-hydroxybutyrate) concentration among PHA monomers increases melting point. Incorporation of specific monomers tends to enhance thermal stability (Khosravi-Darani, Mokhtari, Amai, & Tanaka, 2013).

The chemical composition of PHA is dependent onbiosynthetic pathway and PHA productionenzymes. Classification of PHAdivides them into short chain length PHA (scl

PHA), medium chain length PHA (mcl PHA) and long chain length PHA (lcl PHA) units. Scl PHA, ranging from C3 to C5, include 3-hydroxypropionate, 3-hydroxyvalerate etc. are produced mainly by *Ralstonia* and *Alcaligenes* species (Pantazaki, Papaneophytou, & Lambropoulou, 2011). Mcl PHA, ranging from C6 to C14, include 3-hydroxyhexanoate, 3-hydroxytetradecanoate etc. are produced mainly by *Pseudomonas* species. Whereas lcl PHA have >C14 PHA units (Povolo et al., 2013). Some bacteria also produce copolymers of PHA (Khosravi-Darani et al., 2013). There are four main classes of PHA synthases. Scl PHA are mostly produced by bacteria having synthases belonging to Group I PHA synthases while mcl PHA are typical produced by bacteria having Group II PHA synthases (Povolo et al., 2013). There are three main pathways of PHA production. All three pathways along with other pathways, without exception, need PhaC for successful production of PHA (Tsuge, 2002).

Materials and Methods

Produced water sample was collected and properly labeled with collector's name, site of collection, time of collection and date of collection. Sample was stored at 4oC and transported to laboratory for further characterization. Sample was appropriately analyzed and characterized.Dilutions of sample were prepared by serial dilution method and aseptically spread on Luria Agar plates. Plates were incubated at 37^{o}C for 24 hours. After incubation, colony count was estimated using colony counter. CFU/ml was calculated by using following formula: CFU/ml = $Number of colonies Dilution Factor x Volume plated$

Colonies with distinguishing features were selected from the mixed culture plates to obtain pure colonies. Plates were incubated at 37oC for 24 hours. After incubation, colonial characteristics such as shape, size, elevation, margin, pigmentation, etc. of cultures were recorded.

Isolated strains were screened for PHA production by using PHA detection media supplemented with Nile blue or Nile red(Greenspan et al., 1985), followed by staining of screened colonies with Sudan black dye to visualize PHA granules(Kitamura & Doi, 1994). After incubation, plates were observed under UV illuminator for fluorescence around culture growth(Chaudhry et al., 2011). Bacterial smears were prepared from 24-hour culture of isolated strains cultivated on PHA detection media. Smear was flooded for 15 minutes with Sudan black dye and decolorized with xylene. Slides were washed and counterstained with safranin. Slides were visualized under microscope using magnification 4X, 10X, 40X and 100X (Kitamura & Doi, 1994).

Polyhydroxyalkanoate (PHA) was produced on PHA detection media and extracted from cell mass by using different cheap, renewablecarbon sources e.g. glucose, waste glycerol and animal fat oiland incubated at 37oC for 96 hours. Growth kinetics of isolates were observed and culture densities were measured at 600nm by using spectrophotometer at regular intervals. (Teeka et al., 2010)**.**PHA was extracted using Sodium hypochlorite-SDS method.Dried weight of PHA was weighted and recorded. Percentage of PHA was calculated as follows: % $PHA{=}Weigh\ tof PHA/Weigh\ tof biomass X100$.

PHA production by strains was time profiled at regular intervals over a period of 96 hours.

Selected bacterial strains were used to promote growth of wheat plant, in these experiments produced water was used. The experiments were conducted both at lab and field scale (Khan et al). Polyhydroxyalkanoate (PHA) samples were analyzed by FT-IR around scan range 400 to 4000 cm-1, at Research Centre, Lahore Women's University.

Results and Discussion

Strains were screened for PHA production and 6 out of 13 were found positive. These six strains gave fluorescence on Nile blue and Nile red supplemented PHA detection media. On Nile red, green fluorescence was observed while on Nile blue, blue fluorescence was observed. Binding of dye molecules to PHA granules gives fluorescence (Figure 1). On Sudan staining of these strains, black granules of PHA were observed against pink background (Figure 2).

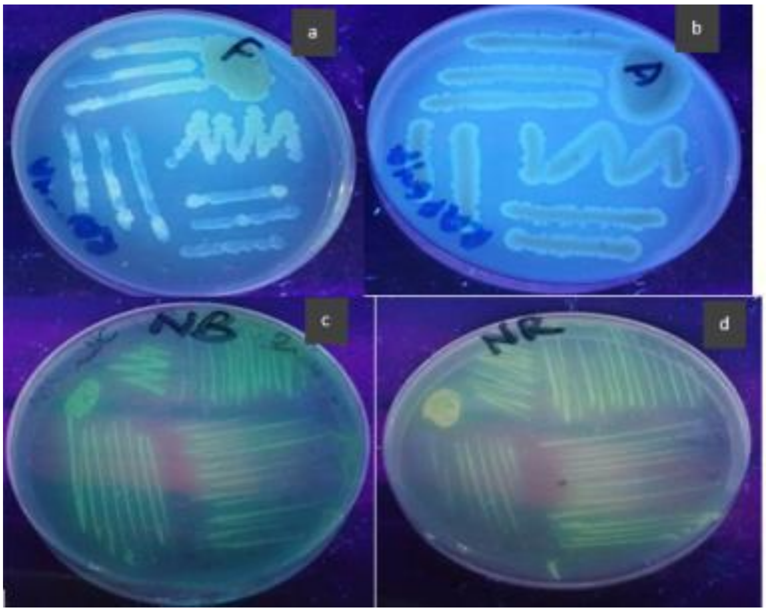

Figure 7 PHA fluorescence on Nile Blue (a, b), Nile red (c, d).

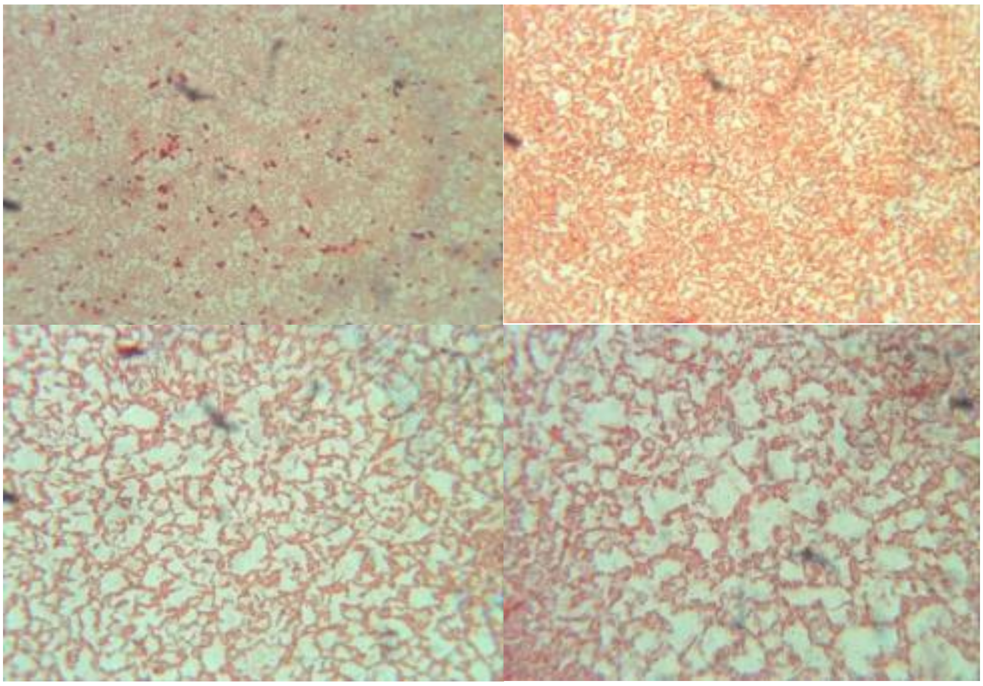

Figure 8 Sudan Staining of PHA granules

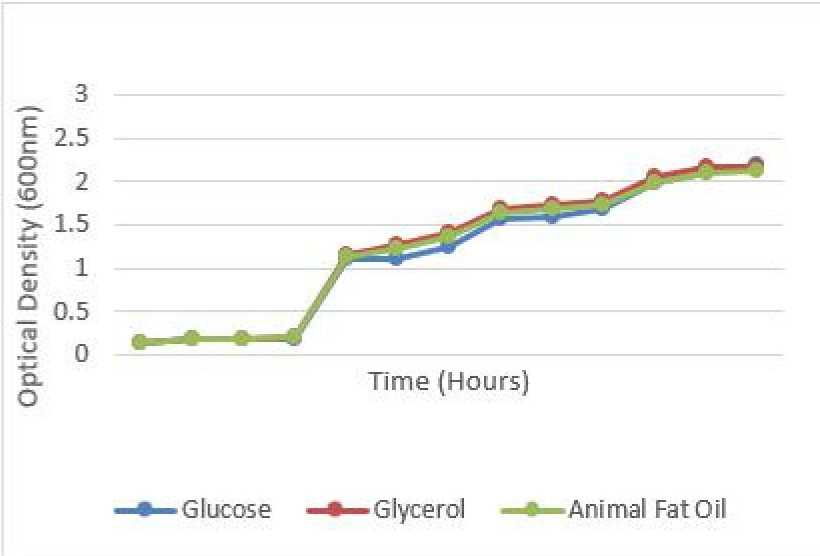

Figure 9 Growth Kinetics of PWA on PHA Detection Media

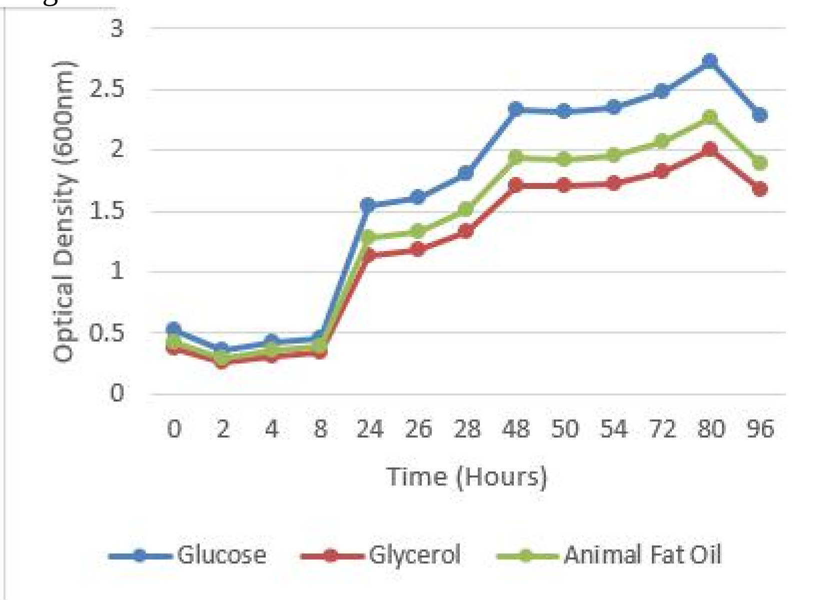

Figure 10 Growth Kinetics of PWC on PHA Detection Media

Overall, highest growth was observed on glucose, followed by animal fat oil and least growth was observed on glycerol supplemented on PHA detection media. All isolated strains were able to grow efficiently on PHA detection media supplemented with these three carbon sources. PWA showed almost equal growth rates on PHA detection media (**Error! Reference source not found.**). PWC showed highest growth rate on glucose, followed by animal fat oil and lowest growth rate on waste glycerol supplemented PHA detection media (**Error! Reference source not found.**). Growth rates of PWC on PHA detection media were slightly higher than growth rates on minimal media.

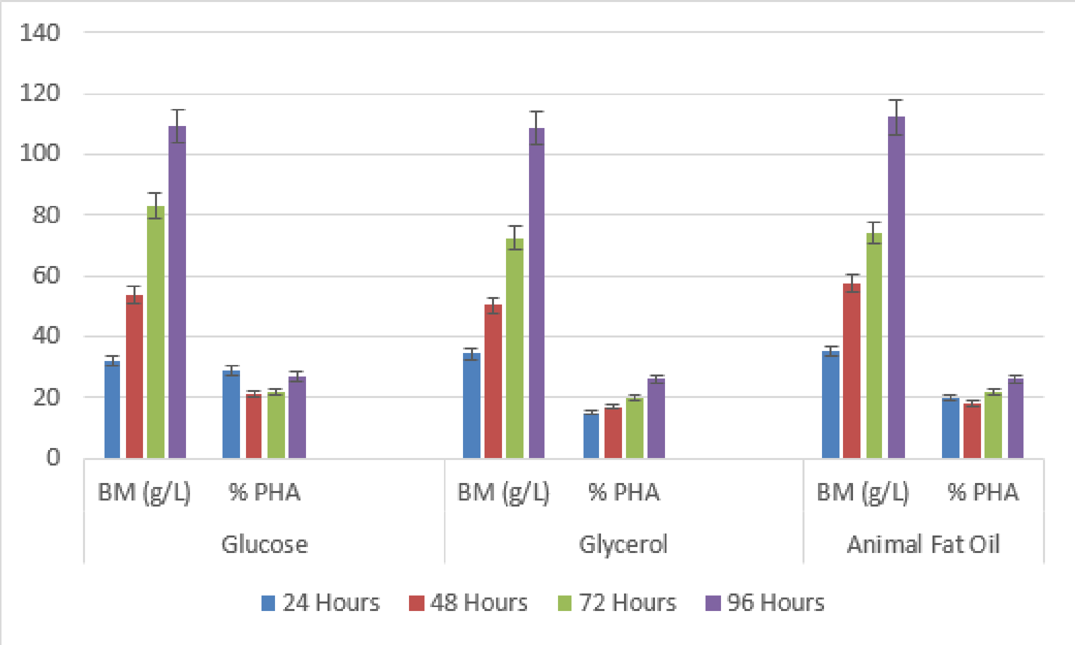

Figure 11 Time profiling for PHA production by PWA on PHA detection media

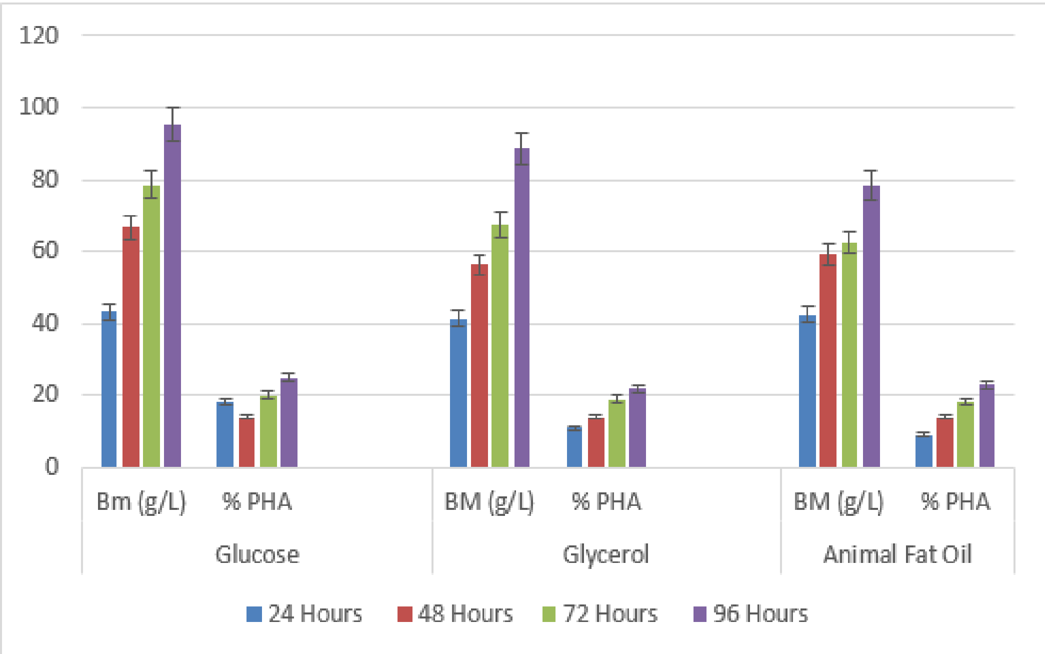

Figure 12 Time profiling for PHA production by PWC on PHA detection media

Time profiling for PWC and PWA indicated overall highest PHA production(Figure 5,6) on using glucose (27%). Films of PHA were obtained for PWA and PWC (Figure7).

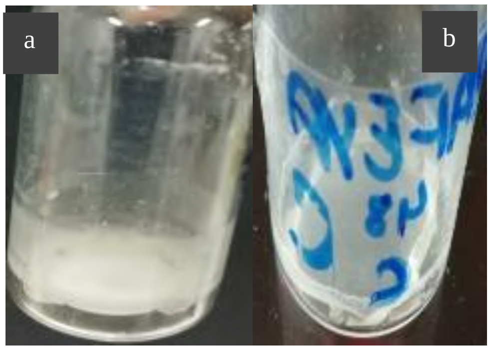

Figure 13 PHA Produced by PWA (a), PWC (b).

Experiments were conducted with wheat for plant microbe interaction (Figure 8). Selected microbial strains PWA and PWC showed an increase in plant growth. Plant microbe interaction experiments were conducted at both lab and field level. Different produced water sample (PW site 1, 2A, 2, 3) were used for these experiments against a control – tap water. Bacterial strains used were PWA and PWC, previously found to be PHA positive strains. These experiments showed more than 90%increase in seed germination rate as compared to control.

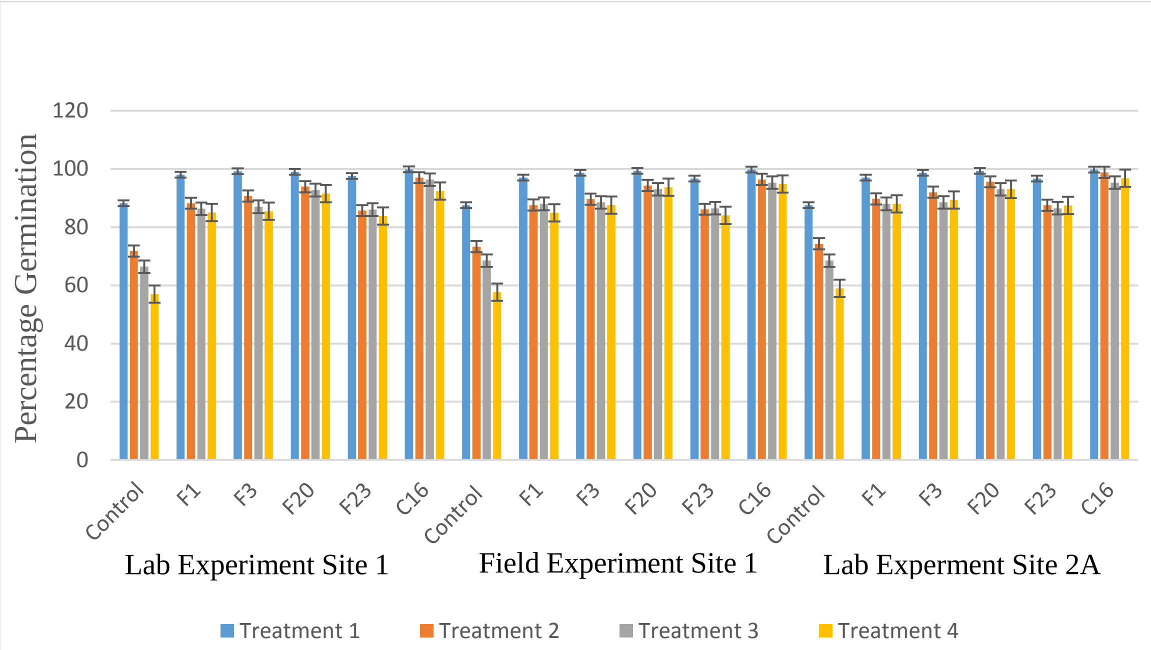

Figure 14 Percentage Germination of Wheat Seedlings in Lab Experiment (with PW Site 1), Field Experiment (with PW Site 1) and Lab Experiment (with PW Site 2 A) of each selected strains

In lab scale experiments maximum increase of 15.78 cm was recorded in shoot length of wheat seedlings. In field experiment the increase was 62.55 cm in shoot length, soil was treated with produced water from site 3. Maximum seedling length of 72.88cm was recorded when PWA and PWC bacterial strains were used along with produced water from site 1.

Conclusions

This study showed the use of complex hydrocarbons by Bacillus sp. from produced water – treated water can be used further in agriculture. Wheat plant – staple food for many countries showed 93% germination rate and 72.87 cm increase in seedling length. Selected strains were also able to produce PHA – a biodegrade-able plastic.

Abstract

The aim of this study was to investigate the quality of composts produced in Lithuania. Physical characteristics, nutrient, heavy metals and organic pollutants contents were determined in green waste, sewage sludge, mixed municipal waste and mixed municipal waste composts after mechanical biological treatment. After analysing physical and chemical parameters of compost quality, it was found that sewage sludge compost contained the highest amounts of nitrogen (2.98%), phosphorus (4.44%) and organic matter (47.6%), and the highest potassium content (1.20%) was found in mixed municipal waste composts after mechanical biological treatment. Having analysed green waste compost samples, it was found that the green waste compost samples of the first year were the most contaminated with heavy metals. Those samples manifested the highest concentrations of all metals investigated during all the research years, except for chromium (Cr). The content of polychlorbiphenyls in different composts varies from a minimum of 0.92 μg kg^{-1} found in green waste compost up to a maximum of 505 μg kg^{-1} in mixed municipal waste compost. PAHs of high molecular weight are predominant in green waste composts, and the ratio between high and low molecular weight PAHs in sewage sludge composts is almost equal. The distribution of low and high molecular weight PAHs in mixed municipal waste composts and composts from mixed municipal waste after mechanical biological treatment is uneven, depending on the different research years this ratio ranged from 93:7 % to 11:89 %.

Keywords: *compost, persistent organic pollutants, heavy metals, nutrients content.*

Introduction

The increasing amount of waste causes the problem of waste disposal, therefore, there is an on-going search for ways to reduce the negative impacts of accumulated waste. The regional waste management centres established in Lithuania implement Directive 2008/98/EC of the European Union, which provides for the reduction of biodegradable waste going to landfills. Each such centre is equipped with composting sites, which compost both tree leaves fallen in autumn and other types of biodegradable waste collected from streets and individual urban residents. Sewage sludge and mixed biodegradable municipal wastes are composted in many regions of Lithuania. Composting is an alternative way of managing biodegradable waste (Saveyn and Eder, 2014, Staugaitis et al., 2015). During composting, biodegradable waste is affected by microorganisms and decomposed, thus a new valuable product – compost – is obtained. High-quality compost is a valuable fertiliser and soil improver. The incorporation of compost into the soil improves its structure, sorption properties, enriches it with the nutrients and helps to fight against soil organic matter degradation (Srivastava et al., 2016). Therefore, as this type of organic fertiliser is gaining popularity, it is particularly important to ascertain both positive and negative effects of it on the environment, soil and plants. Compost can be a source of pollution with heavy metals, persistent organic pollutants and microorganisms (Alvarenga et al., 2017; Gusiatin and Kulikowska, 2014).

The aim of this study was to investigate the quality of composts produced in Lithuania. Physical characteristics, nutrient, heavy metals and organic pollutants contents were determined in green waste (GWC), sewage sludge (SSC), mixed municipal waste (MMWC) and mixed municipal waste composts after mechanical biological treatment (MMWCABMT).

Material and Methods

All chemical parameters of composts were carried out in 2015-2017 years at Agrochemical Research Laboratory of the Lithuanian Research Centre for Agriculture and Forestry.
PH_{H2O} was measured by a combined (mixed) electrode according to EN 13037:2012 (Soil improvers and growing media –determination of pH). Organic matter in the composts was determined by the gravimetric method according to the standard EN 13039:2012 (Soil improvers and growing media – Determination of organic content and ash), total nitrogen (N) was determined by the Kjeldahl nitrogen distiller in accordance with the standard EN 13654-1:2012 (Soil improvers and growing media – Determination of nitrogen. Modified Kjeldahl method), total phosphorus (P_2O_5) and sulphur (S) were determined in *aqua regia* by the spectrometric method according to EN 13650:2001 (Soil improvers and growing media – Extraction of *aqua regia* soluble elements) and EN ISO 11885:2009 (Water quality – Determination of selected elements by inductively coupled plasma optical emission spectrometry (ICP-OES)) using an atomic-emission spectrometer Optima 2100 DV (Perkin Elmer, USA). Organic carbon (C_{org}) was determined by the dry combustion method using a total carbon analyser Liqui TOC II (Elementar, Germany). Total potassium (K) was determined according to EN 13650:2006 (Soil improvers and growing media – Extraction of *aqua regia* soluble elements) and ISO 9964-3:1998 (Water quality – Determination of sodium and potassium – Part 3: Determination of sodium and potassium by flame emission spectrometry) using a flame emission photometer PFP7 (Jenway, UK). Heavy metals in composts were determined by the standards ISO 11466:2016 (Soil quality – Extraction of trace elements soluble in *aqua regia*) and ISO 11047:2015 (Soil quality – Determination of cadmium, chromium, cobalt, copper, lead, manganese, nickel and zinc – Flame and electrothermal atomic absorption spectrometric methods) using the atomic-emission spectrometer Optima 2100 DV (Perkin Elmer). Non-instrumental methods were used for the analyses of dry matter, electrical conductivity and laboratory compact bulk density. The quantity of polycyclic aromatic hydrocarbons (PAHs) and polychlorbiphenyls (PCBs) was determined according to laboratory-developed methods LVP G-11(Determination of polycyclic aromatic hydrocarbons in soil improvers by liquid chromatography) and LVP G-12 (Determination of polychlorbiphenyls in soil improvers by gas chromatography with an electron capture detector) respectively.
Composition and preparation of composts are described in the publication (Barcauskaitė, 2019).

Results and discussion

After analysing physical and chemical parameters of compost quality, it was found that sewage sludge compost contained the highest amounts of nitrogen (2.98%), phosphorus (4.44%) and organic matter (47.6%), and the highest potassium content (1.20%) was found in mixed municipal waste composts after mechanical biological treatment. Of all the composts tested, green waste composts had the lowest content of the following nutrients: nitrogen, phosphorus, potassium, calcium, magnesium and sulfur. In all tested composts, pH was moderately alkaline, except for sewage sludge compost during the second year of research. Concentrations of 7 heavy metals (Cr, Zn, Cd, Ni, Pb, Cu and Hg) were determined in composts of different origin. The results obtained are presented in Tables 1–4.

Table 1. Total amount of heavy metals in green waste compost, mg kg^{-1} d.w.

Heavy metals	Year		
	2015	2016	2017
Chromium (Cr)	12.5±0.028	13.8±6.24	12.1±0.42

Copper (Cu)	298±9.9	338±153.3

Having analysed green waste compost samples, it was found that the green waste compost samples of the first year were the most contaminated with heavy metals. Those samples manifested the highest concentrations of all metals investigated during all the research years, except for chromium (Cr).

The amounts of seven PCBs most commonly described in scientific articles have been investigated in green waste, sewage sludge, mixed municipal waste composts and composts of mixed municipal waste after mechanical biological treatment. The amounts of PCB 28, PCB 52, PCB 101, PCB 118, PCB 138, PCB 153 and PCB 180 have been determined. The qualitative analysis for various PCB homologues is equally important to perform as is to study the total amount of them. The durability level and resistance to the effects of microorganisms in PCB molecules depend on the number and position of chlorine atoms (Correa et al., 2010; Pěnčíková et al., 2018). The average distribution of seven different PCBs in composts of different origin produced in Lithuania is depicted in Figure 1.

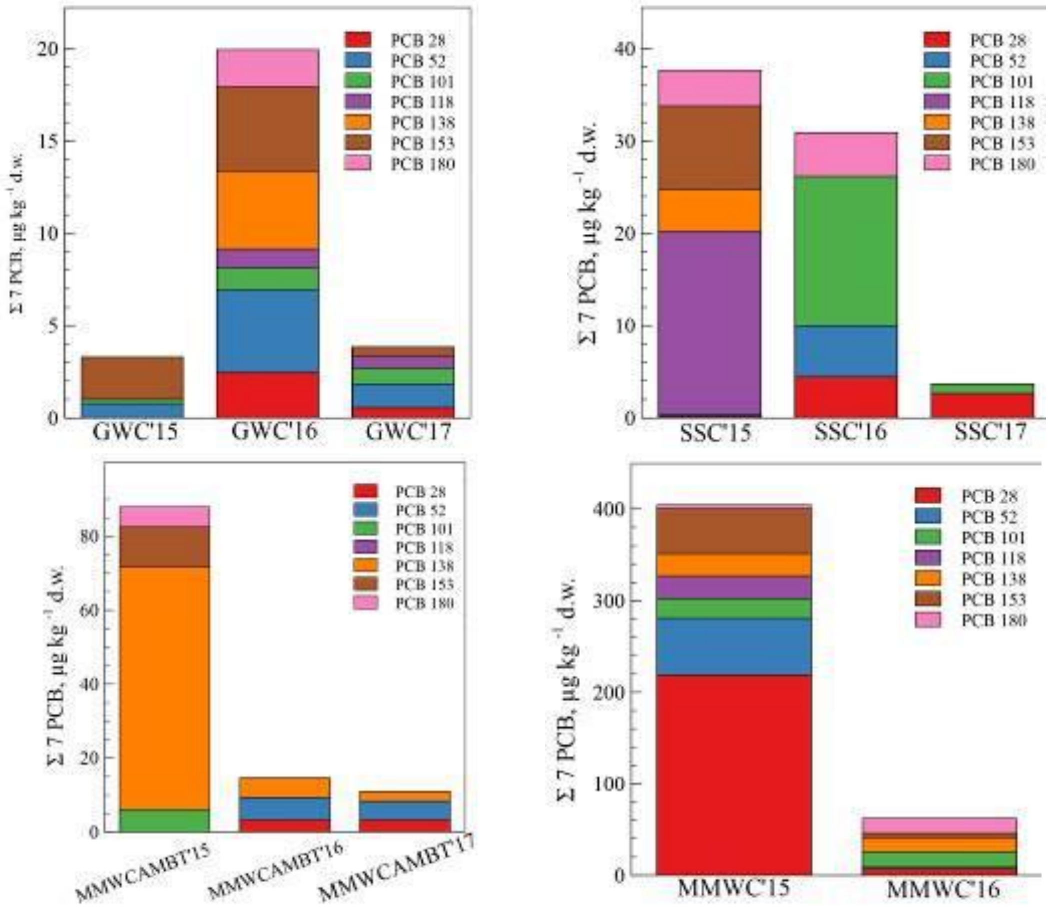

Figure 2. Average distribution of seven different PCBs in composts of different origin

During the research period (2015–2017), a quantitative analysis was performed on 15 PAHs included in the list of priority pollutants by US Environmental Protection Agency (Kafilzadeh, et al., 2015). The dominant PAH homologues in green waste composts were fluoranthene in the first research year, and pyrene and benzo(g,h,i)perylene during the second and third year, respectively. The highest amount of dibenzo(a,h)anthracene was found in sewage sludge composts during the first study year, in the second year the dominant compounds were fluoranthene and phenanthrene compounds, and during the third year, they were dibenzo(a,h)anthracene and fluoranthene. For mixed municipal waste composts after mechanical biological treatment, fluorine dominated during the first and second year of research, which accounted for 82% and 24% of the total PAH content found, respectively. In the third research year the highest levels of pyrene were found. Fluoranthene, pyrene and fluorine were dominant in mixed municipal waste composts.

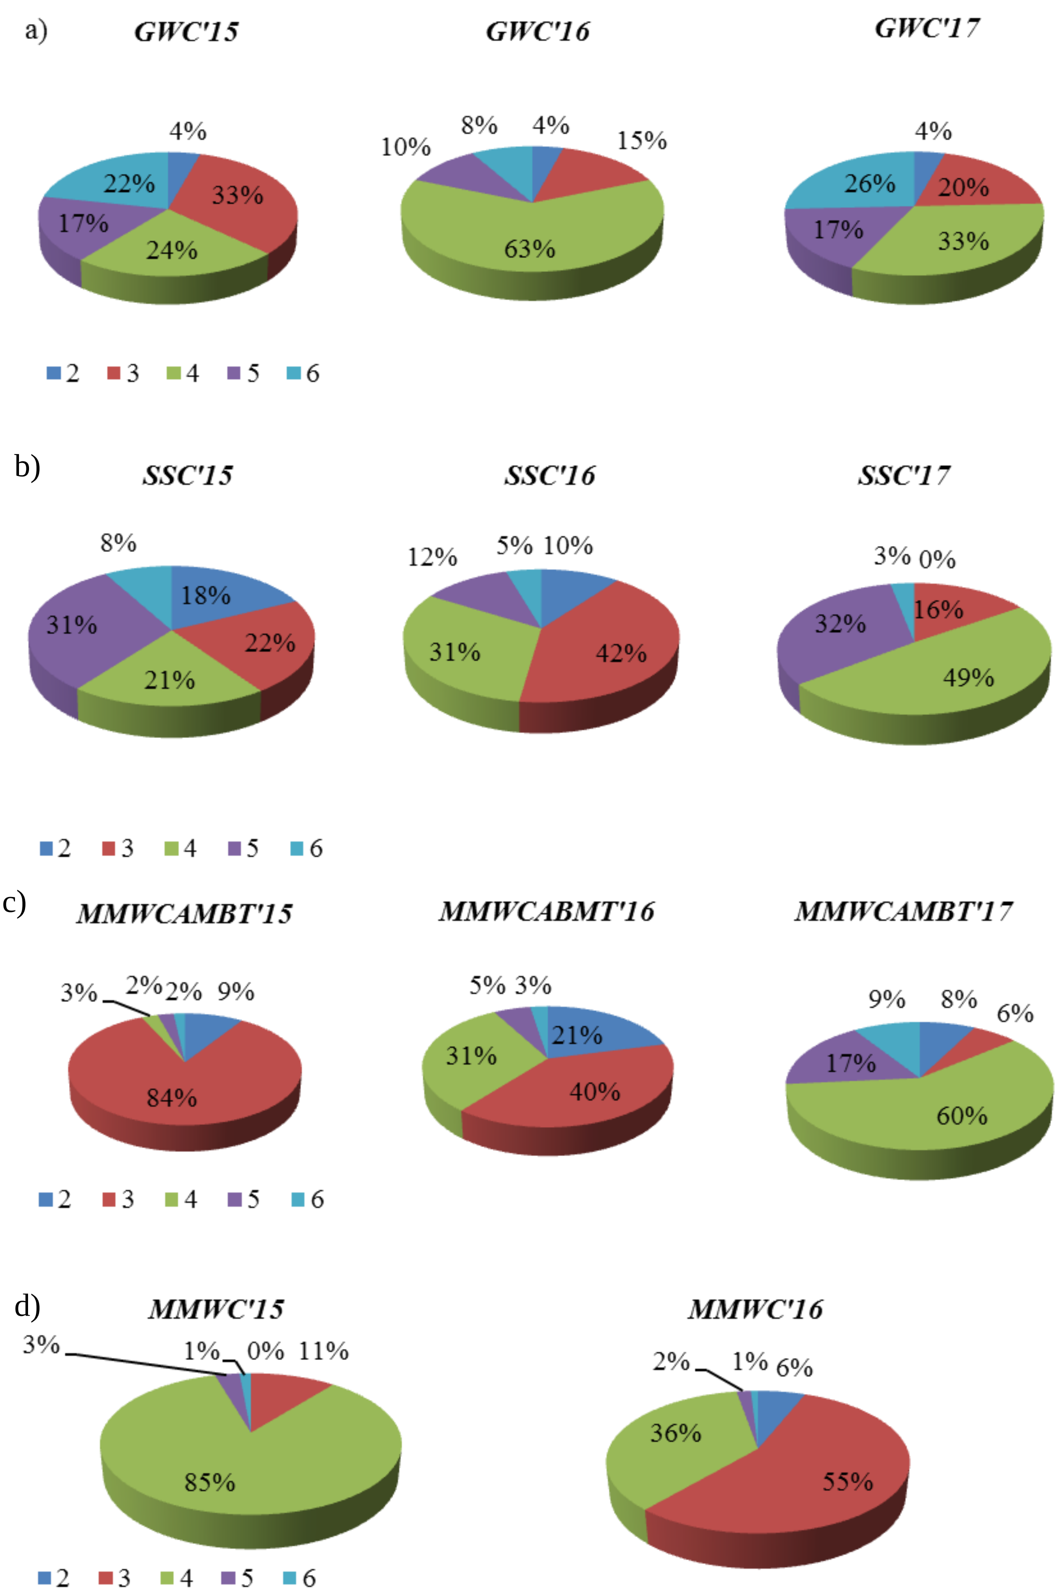

Figure 2. Distribution of polycyclic aromatic hydrocarbons in different kinds of compost according to benzene ring number

.

According to the number of aromatic rings, polycyclic aromatic hydrocarbons are classified as low molecular weight (2–3 rings) and high molecular weight (4–6 rings) compounds (Wang et al., 2007). The number of aromatic rings in a polycyclic aromatic hydrocarbon molecule determines their biological and physical biodegradation properties (Melnyk et al., 2015). As shown in Figure 2, high molecular weight PAHs dominated in green waste composts (a). They accounted for 63%, 81% and 76% in a respective research year. Low and high molecular weight PAHs were distributed almost equally (40% and 60% in 2015, 52% and 48% in 2016) in the analysed sewage sludge composts (b), except for 2017, when low molecular weight PAHs were determined to account for 16 %, while high molecular weight PAHs – 84%. Low and high molecular weight PAHs were not distributed evenly in mixed municipal waste composts and composts from mixed municipal wastes after mechanical biological treatment. For mixed municipal waste composts, low and high molecular weight PAHs were found to be 93% and 7% in the first year, 61% and 39% in the second year, and 14% and 86% during the third year, respectively.

Conclusions

Having performed the chemical analysis of composts made from using green waste, sewage sludge, mixed municipal waste after mechanical biological treatment and mixed municipal waste, the highest amounts of nitrogen, phosphorus and organic matter were found in sewage sludge composts, and highest potassium levels – in mixed municipal waste compost after mechanical biological treatment. The content of polychlorbiphenyls in different composts varies from a minimum of 0.92 μg kg^{-1} found in green waste compost up to a maximum of 505 μg kg^{-1} in mixed municipal waste compost. PAHs of high molecular weight are predominant in green waste composts, and the ratio between high and low molecular weight PAHs in sewage sludge composts is almost equal. The distribution of low and high molecular weight PAHs in mixed municipal waste composts and composts from mixed municipal waste after mechanical biological treatment is uneven, depending on the different research years this ratio ranged from 93:7 % to 11:89 %.

Abstract
In this experiment, 180 day-old chickens of Ross 308 and Cobb 500 broiler hybrids were used in a 42-day experiment to determine the effects of genotype and sex on productive performance and carcass characteristics. Chickens were housed in a 3-etage cage technology with proportion 75x50 cm (0.375 m^2) for each cage in half-operating conditions. Feed and water were provided ad libitum. We recorded body weight, body weight gain, feed intake, feed conversion ratio and mortality rate. Genotype had a significant effect ($p<0.05$) on feed conversion ratio, Cobb 500 being a better efficient in converting feed than Ross 308. Males were heavier at 42 days of age, gained more body weight, consumed more feed and utilized the feed more efficiently compared with females but had a higher mortality rate. There were significant genotype × sex interaction effects in 42-day body weight, body weight gain, feed intake and mortality rate. In case of carcass characteristics, genotype significantly affected ($p<0.05$) liver and gizzard weights with a heavier values in Cobb 500 than Ross 308. Sex significantly affected ($p<0.05$) slaughter, carcass, breast, legs, liver, gizzard weights with higher values for males than females. In contrast, abdominal fat weight was significantly higher ($p<0.05$) for females compared with males. Genotype × sex interaction effects significantly influenced carcass, breast, legs and liver weights.

Keywords: *chicken, genotype, sex, performance, carcass*

Introduction
The modern broiler chicken production is an extensive and rapidly developing sector, supplying the market with relatively cheap and high-quality dietetic food. Due to contemporary selection programmes, a considerable improvement of weight gain, feed conversion, slaughter yield and breast meat yields were achieved during the past decades (Hristakieva *et al.*, 2014). The aforementioned traits depend on numerous factors, including the genotype and the sex. Many researchers have reported a substantial effect of the genotype on body weight (Razuki *et al.*, 2011), feed conversion, carcass composition (Marcato *et al.*, 2006), carcass weight (Rondelli *et al.*, 2003) and abdominal fat (Hristakieva *et al.*, 2014).
It has been reported that sex affects performance traits of chickens such as body weight, body weight gain, feed intake and feed conversion ratio (Ajayi and Ejiofor, 2009). Sex also significantly affects carcass traits such as carcass composition, proportion of wing, thigh, neck and carcass fat and carcass meat with higher values in males than females (Siaga *et al.*, 2017).
The aim of this study was to assess the effect of genotype and sex on productive performance and carcass characteristics broiler chickens reared under cage technology.

Material and Methods

The experiment was realised in experimental base of Department of Poultry Science and Small Farm Animals on two broiler chicken hybrids (Ross 308 and Cobb 500). Broiler chickens were housed in a 3-etage cage technology (MBD, Czech Republic) consisted of 18 cages with proportion 75x50 cm (0.375 m^2) for each cage. Chickens were fed *ad libitum* with complete feed mixtures – starter (CP min. 210.00 g/kg, ME min. 12.00 g/kg) in powdery form from Day1 to Day 21 and grower (CP min. 190.00 g/kg, ME min. 12.00 g/.kg) in granular form from Day 22 to Day 42 (Boskop, a.s., Trencin, Slovak Republic).

Temperatures were maintained at 33 °C in the 1^{st} week and this was reduced by 2 °C every week then decrease gradually until reach 23 °C in the 6^{th} week. Moisture was retained during fattening period between 50 to 60%. Lighting in the poultry house first day was 24 hours and by starting the 5 day became permanent and 23 hours, used the 40 watt bulbs.

Totally 45 male and 45 female one-day-old chickens each of Ross 308 and Cobb 500 hybrids were kept in this experiment. During the experiment broiler chickens were weighted for individual body weight at 1, 7, 21, 35 and 42 day of age and body weight gain were calculated as the difference between the final and initial chicken weight. Feed consumption, feed conversion ratio and mortality rate were recorded. In 42 day of fattening, representative 10 chickens with body weight similar to the mean were chosen from each group for slaughter weighed and subjected to a 12-hours feed withdrawal. After slaughter, carcasses were weighed and subjected to simplified dissection. The breast, leg (drumstick + thigh), back and wings were collected and weighed. In addition to carcass weight, liver (without gall bladder), gizzard (empty gizzard), heart and abdominal fat weights were recorded individually.

Data were subjected to analysis of variance using one way ANOVA procedure of the statistical system at JASP 0.8.6 software (JASP, 2018). Differences between means were ranked by Duncan's multiple range test (Duncan, 1955).

Results and Discussion

As shown in Tables from 1 to 3, broiler genotype significantly affected Day 7 and Day 21 body weights and feed consumption. In contrast, body weight gain, feed conversion ratio and mortality rate were no influenced by genotype. Chicken genotype affected feed conversion ratio but did not affect Day 35 body weight - Cobb utilized feed more efficiently than Ross, but the genotypes did not differ in Day 42 body weight, body weight gain, feed consumption, and mortality rate. There were significant genotype × sex interaction effects on body weight gain, feed intake, feed conversion ratio, and mortality rate. Our results are similar to those published Benyi *et al.* (2015) but no consistent with findings of Castellini *et al.* (2014), who reported significant differences in feed conversion ratio among hybrids of broiler chickens.

Males were heavier at Day 7, consumed more feed, utilized the feed more efficiently, gained more body weight, and were heavier in Day 21 in comparison with females. We recorded significant genotype × sex interaction effects on Day 21 body weight and body weight gain from Day 7 to Day 21 ($P<0.05$). Sex influenced Day 35 body weight, body weight gain, feed consumption, and feed conversion ratio with better means for males than females.

The two sexes however did not differ significantly in mortality rate. Males consumed more feed and utilized it less efficiently. There were significant genotype × sex interaction effects on 35-day body weight, body weight gain, feed consumption, and feed conversion ratio. Sex significantly affected Day 42 body weight, body weight gain, feed consumption, and feed conversion ratio with a better performance in males than females. There were significant genotype × sex interaction effects in Day 42 on body weight, body weight gain and feed consumption (Table 1 to 3). Similar findings recording Thutwa *et al.* (2012).

The data of carcass characteristics in Table 4 shows that genotype had no significant effects on all the traits. Sex affected wing weight, carcass weight, back weight, and leg weight but did not affect breast weight. Males were heavier than females in carcass, back, wing, and leg weights. Genotype × sex interactions significantly affected carcass, breast, back, wing, and leg weights. Similarly results found Fernandes *et al.* (2013) who found no significant differences in carcass yields of Ross, Cobb, Hubbard and Arbor Acres chicken hybrids.

The results in Table 5 show that broiler chicken genotype affected liver weight. Sex influenced liver, gizzard and abdominal fat weights but we noted no significant effect on heart weight. Males were heavier than females in liver and gizzard weights but deposited less abdominal fat than females. Genotype × sex interactions affected liver weight but had insignificant effects on gizzard, heart and abdominal fat weights. With regard to giblets, our results agree with that of Olawumi *et al.* (2012) that breed × sex interactions have insignificant effects on liver weight and gizzard weight, both sexes within and between breeds recorded similar mean values, and this result is contrary to the results of Ojedapo *et al.* (2008) who reported significant strain × sex interaction effects on these traits.

Conclusion

In conclusion, we can state that broiler chickens no significantly affected final body weight, body weight gain, feed intake, and mortality rate, although, Cobb 500 chickens utilized feed more efficiently compared Ross 308 chickens. In cause of sex, males were heavier in the end of fattening period, gained more body weight, utilized feed more efficiently but consumed more feed and had a higher mortality rate in comparison with females. From characteristics, hybrid influenced liver and gizzard weights. Males deposited less abdominal fat compared with females. We recorded significant genotype × sex interaction effects on all the carcass traits measured except gizzard, heart, and abdominal fat weights.

Abstract

The aim of research was represented by conducting of some research activities aiming to evaluate the lactogenic capacity for the experimental batches, as an effect of cross-breeding between goats belonging to local breed Carpatina and bucks from Anglo Nubian and French Alpine breeds. Estimation of milk production was done in according with International Committee for Animal Recording (AT4 method) and statistical analysis was performed using the Restricted Maximum Likelihood Method. In case of effectuated analysis for evaluation of ameliorative effect of milk production obtained from F1 half-breed females, resulted by cross-breeding of Anglo Nubian breed bucks with local females, a real absolute difference for total milk production of 17.74 milk kg could be observed, difference which have an increased statistical significance degree for $p<0.01$. In the case of batch formed by F1 half-breed females, resulted by cross-breeding of French Alpine breed bucks with Carpatina local goats, a real absolute differences of 23.30 milk kg was found, being distinctively significant for $p<0.01$. The obtained results show that effect due to heterosis have a higher manifestation on productive performances for F1 half-breed females resulted by cross-breeding of Carpatina breed females with French Alpine bucks. According to this observation we could say that Frennch Alpine breed have a higher ameliorative degree on milk production.

Introduction

Sheep and goat farming in the EU faces some economic, structural and other difficulties, which have led to a steady decrease in total staff in many member countries. Thus, at the level of the European Union, the decrease in the number of herds was 16% during period 2000-2016, being accelerated in the periods when some contagious diseases broke out, as well as after some major changes of the financing schemes of the farms from the Union European or national resources. In order to encourage the revival of activities in this field, there are several EU support instruments to support production capacity and deliver not only food, but also public goods such as the use of natural resources and the preservation of biodiversity. However, given the low profitability and the fact that small ruminants are concentrated mainly in less favoured areas, some support measures that are more attractive for farmers need to be developed and implemented in order to revival the growth activity (Pascal, 2015). In the current context, the discussion on the Common Agricultural Policy concerns the post-2020 period and aims to adopt communication and promotion measures to strengthen the sector's position in the EU and respect for consumer demand in this geographical area (European Parliamentary Research Service, 2017). At the level of the European continent, the Mediterranean and Black Sea countries are less important for dairy goats than for sheep milk. These countries produce 10.5% of world production of goat milk and produce 19.1% of goat's milk in the world (FAOSTAT, 2018). Among them, France (20.7%, 715 l/doe), Spain (14.1%, 328 l/doe), Greece (13.2%; 134 l/doe) and Turkey (11.8%, 73 l/doe) are the current leaders in the production of goat milk in the area followed by the Russian Federation (8.6%, 330 l/doe), Ukraine (7.8%, 500 l/doe) and Algeria (7.9%, 85 l/doe) (Pulina et al., 2018). In this context, Romania wants to join these countries and has adopted a number of support measures that have led to an increase in total goat population in 2015 compared to 2005 by more than 27% (Pascal et al. 2017). The level reached has also led to the application of research and technical activities to attract and improve milk production. For this purpose, this research was also carried out, the main objective being to assess the effect of heterosis due to crosses between native females of Carpatina breed with Anglo Nubian and French Alpine goats.

Material and Methods

The biological material was represented by different populations of goats belonging to different breeds, namely the Carpatina native breed (M) and some half-breeds from the first-generation resulting from the crossbreeding of the local female breed with Anglo-Nubian (L1) and French Alpine (L2) males.

In order to eliminate the influence of external factors on productive performances homogeneous lots belonging to the three researched populations were constituted, each batch consisting of 25 females at the first lactation. The maintenance, feeding conditions, as well as the evaluation period of the researched characters, were performed within the same time frame.

In order to compare the results and to determine the cross-breeding effect, in particular on the milk production capacity, the data obtained as a result of the application of the control of the productive performances placed at equal intervals in the lactation was used.

The performance evaluation for milk production resulted in the analyzed lactation was based on the application of successive periodic inspections, and using for the lactation period the Nica method and for the milking period was exclusively applied the method AT_4 in compliance with the technical specifications suggested by International Committee for Animal Recording. Estimation of the average total production of milk was carried out using the Fleischmann method.

$$\text{Milk yield [kg]} = \mathrm{L}_1.\mathrm{int}_1 + \sum_{i=2an}\left(\frac{\mathrm{L}_i + \mathrm{L}_{i-1}}{2}.\mathrm{int}_i\right) + \mathrm{L}_n.14$$

where:
L_1 = milk yield of the 1st monthly test;
L_i = milk yield of the ith monthly test (i = 1,..., n);
L_n = milk yield of the last test;
int_1 = number of days from kidding to 1st monthly test;
int_i= number of days between monthly tests (i-1) and i (i = 1,...,n);
n = total number of monthly test for a specific animal.

Data were statistically evaluated with the algorithm REML (REstricted Maximum Likelihood), which provides the achievements of the statistical parametric estimators within the normal range.

Results and Discussion

Genetic improvement programs for goats are a common practice, the goal being to identify solutions, methods, ways and technologies that can increase the lactogenic potential. Typically, these programs include characters and features that are economically important to achieve greater productivity, higher income, and lower cost per product unit (Taftă et al., 1997).

For practice, the ameliorative effect due to the application of cross-breeding programs is positive, but the final effect depends mainly on the participating breeds, but also on their genetic baggage for the characters that are subject to change. The option of introducing into the crossbreeding scheme of the breeds was motivated by the fact that the literature shows different results showing that these breeds improve not only the milk production (Serradilla, 2001) but also the precocity and growth intensity (Moman M.S. et al., 2012), but also some

reproductive indices specific to the reproduction activity (Aboul Nagaa et al., 2016) in different goat populations in less favourable areas.
Also, in an extensive study, Ricordeau (1981) analyzed the results of increased milk production as a result of crossbreeding between indigenous breeds of specialized breeds and concludes that when it is desired to increase milk production in a shorter time; crossing is a favourable technical solution.
As regards to the Anglo Nubian goats, their role has increased over the last period of time because it has been found to react positively to crossings with local breeds that are less productive. This is the reason why Nubian goats have been continuously imported into China for the past decades, to improve the performance of local breed production (Yuan et al., 2017). Understanding the genetic basis underlying the distinct phenotypes of these two breeds will be a perquisite for new breed selection and customizing strategies for cross breeding.
After the statistical processing of the data obtained from the application of the productive control, there was a tendency to show a positive type of heterosis for the quantity of milk in both half-breed female populations (L1 and L2) compared to the performance obtained from the females of Carpatina breed (M), being at the first lactation.
This finding is supported by the fact that both half-bred female groups gave milk yields higher with 10.36% in the case of those resulted from the crossing with Anglo Nubian goats and with 13.18% at the group obtained with the French Alpine (table 1 and figure 2), both differences recording a high degree of statistical significance for $p \geq 0.001$.

Table 1. Total average milk production obtained in the controlled lactation (kg)

Specification		M	L1	L2
n		25	25	25
$\overline{x}$		153.48	171.22	176.78
$\pm s_{\overline{x}}$		1.18	1.51	2.31
V%		14.43	13.34	13.09
s		11.031	14.221	14.305
Limits	Minimum	95.41	108.45	147.10
	Maximum	198.33	189.02	236.50
Difference and its signification for the average total milk production				
Batches	Difference ±	Statistical significance of the difference		
M – L1	- 17.74	*** - F (21.6622) > Fα (12.0831) for 0.001		
L1 – L2	+ 30.33	*** - F (28.2822) > Fα (11.3487) for 0.001		
M – L2	- 49.41	*** - F (31.2247) > Fα (16.6120) for 0.001		

In the case of the analysis performed to determine the ameliorative effect of milk production obtained from the first generation in the half-breed females resulted from the crossing of the Anglo Nubian goats with the local Carpatina females, there is a real absolute difference between the total milk production obtained from the controlled lactation, of 17.74 kg of milk, a difference with a high degree of statistical significance for $p<0.01\%$.

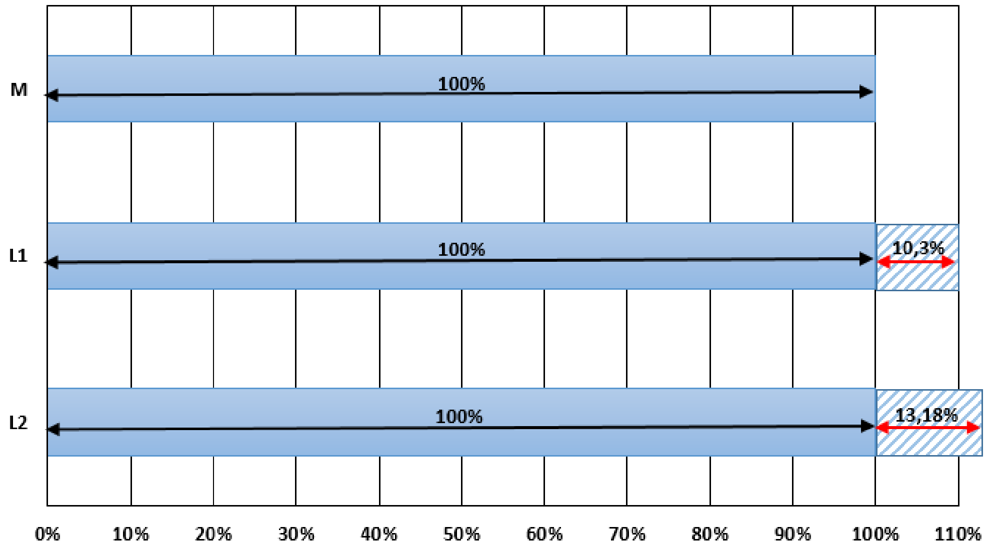

Figure 1. Graphical representation of the differences between groups for productive performance recorded in the controlled lactation

In the case of crossbreeding of French Alpine goats with local females, the real difference between the milk production level is of 23.30 kg of milk and was distinctly significant for $p<0.01$. However, results obtained in other researches, but carried out on other groups of half-breed females obtained using French Alpine goats, show the ability to improve milk production right from the first lactation. Thus, in a study conducted in 2017 by Anghel et al., 2017, it is found that for the half-breed goats of French Alpine x Carpatina it is noted an increase of the milk quantity starting with the second month of lactation, when the maximum was reached. The experimental data proved that both half-breed French Alpine x Carpatina (table 1), and also those of Saanen x Carpatina reach the prediction value at the establishment of the ratio, of 2 kg milk/day, starting with the second day of lactation.

Conclusions

Because in both half-bred lots there is a manifestation of the positive type of heterosis for the quantity of milk obtained at the first lactation from the half-bred females resulted in F_1 it can be said that there is a high degree of genetic combinability among the participating breeds;
Both half-breed female lots gave milk yields higher with 10.44% for those resulted by the use of Anglo Nubian goats and with 11.56% for the lot obtained with the French Alpine;
The fact that the half-bred population obtained by using French Alpine goats produces a production of more than 200 litres in a normal lactation, recommends its use in the improvement of this character in goats.

Abstract

The aim of this study was to determine the microelements content of grape pomace, grape stem and grape bunch of three different cultivars of *Vitis vinifera sp*. (Green Veltliner, Pinot Blanc and Zweigelt) from two countries as a possible sources for animal nutrition. Mineral profile analysis was performed by using the High Resolution Continuum Source Atomic Absorption Spectrometer contrAA 700 for zinc, copper, iron, manganese. Significant differences ($P<0.05$) in mineral composition of analyzed samples were found between the countries, as well as between the cultivars within countries. The grape pomace samples from Slovakia and Austria had significantly different ($P<0.05$) content of all the studied microelements, except for zinc. In the case of grape stems significant differences ($P<0.05$) for copper and manganese content were found. The grape bunches from two counties significantly differed ($P<0.05$) in copper, iron and zinc content. The Austrian grape pomaces, as well as grape stems had significantly different ($P<0.05$) copper and iron content, while the bunch samples differed significantly ($P<0.05$) only in iron content. Between Slovakian grape pomaces significant differences ($P<0.05$) in copper and zinc content were found. All the stem samples from Slovakia differed significantly ($P<0.05$) only in zinc content and the bunches had significantly different ($P<0.05$) copper content. These results indicate a significant impact of the grape variety and location on the mineral profile of grape by-products.

Keywords: *Microelements, Grape pomace, Grape stem, Grape bunch.*

Introduction

Grape is the world's largest fruit crop, with an annual production of more than 75 million tonnes (OIV, 2017). The vast majority of the total grape production (75%) is used to produce wine (García-Lomillo, Gonzáles-San José, 2017). The two main by-products of grape processing are pomace and stalks (Makris et al., 2007). Grape pomace accounts for about 20-25% of the weight of the grape crushed for wine production (Yu, Ahmedna, 2013), the quantity of stems varies between 1.4% and 7% of the raw matter processed (Souquet et al., 2000). These by-products are currently not considered to be profitable and are most commonly used as fertilizer, left on open spaces or burned, which can lead to environmental problems ranging from surface and groundwater pollution to foul odours (Rondeau et al., 2013, Bekhit et al., 2016). The use of these products for fertilizers or composts on soils can cause an increase in nitrogen leaching and oxygen depletion due to the presence of tannins and other compounds (Bekhit et al., 2016). With respect to animal feed, the nutritional value and the digestibility of these by-products is, due to high fiber content, generally low. However, because of the growing interest in environmentally friendly waste-free technologies and minimizing the cost of processing by-products from wine industry, innovative procedures are being introduced (Brenes et al., 2016, Gálik et al., 2018). Many experiments showed, that these products can be used a substantial source of certain nutrients and biologically active compounds in animal nutrition (Viveros et al., 2011, Nistor et al., 2014, Teixeira et al., 2014, Chamorro et al., 2015, Domíngues et al., 2016, Kerasioti el al., 2017, Chedea et al., 2018). This alternative may contribute to reduce winery residuals, improve environmental aspects, so as to reduce production costs and offer a new way to diversify the production (García-Lomillo, Gonzáles-San José, 2017). The composition of these by-products may vary depending on extrinsic factors such as edaphoclimatic conditions and viticultural practices, as well as intrinsic factors such as variety and maturity of the grapes (García-Lomillo, Gonzáles-San José, 2017). Therefore, their composition should be determined on a case-by-case basis (Ziarati et al., 2017). In this study, we hypothesize that the mineral profile of grape pomace (GP), grape stem (GS) and grape bunch (GB) is closely related to the grape variety and differences in their composition can be found due to the country of origin. The aim of this study was to determine the microelements content of GP, GS and GB of three different cultivars of *Vitis vinifera sp*. - Green Veltliner (GV), Pinot Blanc (PB) and Zweigelt (ZW) from two countries as a possible sources for animal nutrition.

Material and Methods

The pomace, as a by-product of juice pressing in wine industry, mainly contained of residual grape skin, seeds and pulps. GS were only rachis, peduncle and pedicels after removing grape berries. In total, 54 samples from 3 varieties from 6 different locations were analysed. Laboratory samples were processed in the Laboratory of Quality and Nutritive Value of Feeds at the Department of Animal Nutrition at the Slovak Agricultural University in Nitra by standard laboratory methods and procedures (EC No 152/2009). The contents of mineral nutrients were determined by High Resolution Continuum Source Atomic Absorption Spectrometer contrAA 700 (ANALYTIK JENA). The determination of individual elements content was based on the absorptions measured at the following wavelengths: zinc (Zn) at 213.9 nm, copper (Cu) at 324.7 nm, iron (Fe) at 248.3 nm and manganese (Mn) at 279.5 nm. To calculate basic statistic characteristics, to determine significance of differences and to compare results one-way ANOVA and t-test were performed at $P<0.05$ level. The SAS statistical package was used (SAS Inc., New York City, USA).

Results and Discussion

Microelemet profile of grape by-products from Slovakia in shown in Table 1. Between GP significant differences ($P<0.05$) in Cu and Zn content were found. GP from GV had the highest Cu and Fe content and the lowest content of Mn and Zn. On the other hand, the concentration of these microelement was exactly the opposite in ZW, except for Zn. The highest amount of Zn was detected for PB. All stem samples from Slovakia differed significantly ($P<0.05$) only in Zn content. Similarly to GP, GS from GV had the highest Cu and the lowest Zn content and stem from ZW was the richest in Mn content with the lowest Fe concentration. Stem from PB contained the highest amount of Fe and Zn and the lowest amount of Cu and Mn. Slovakian bunches had significantly different ($P<0.05$) Cu content. The lowest concentration of Mn was found for GV, bunch from PB had the lowest amount Cu, Fe and Zn. The highest content of the studied microelements was measured for ZW. Interestingly, the lowest number of measured trace elements was detected in bunches compared to their contents in pomaces and stalks.

Table 1. Microelemet profile of grape by-products from Slovakia (mg.kg^{-1})

		Green Veltliner	Pinot Blanc	Zweigelt
		Mean±Standard Deviation		
Cu	pomace	25.26±0.6^{a}	21.29±0.48^{b}	16.68±0.71^{c}
	stems	30.78±0.32^{a}	12.90±2.22^{b}	13.07±0.71^{b}
	bunch	9.67±0.37^{a}	4.93±0.32^{b}	16.24±0.01^{c}
Fe	pomace	152.86±2.82^{a}	103.49±0.57^{b}	100.38±0.02^{b}
	stems	115.03±1.08^{a}	153.77±19.12^{b}	98.72±1.28^{a}
	bunch	35.36±2.39^{ab}	31.79±1.85^{b}	39.30±0.13^{a}
Mn	pomace	14.35±0.54^{a}	16.95±1.06^{b}	17.81±0.63^{b}
	stems	42.32±1.81^{a}	40.11±0.21^{a}	47.72±0.80^{b}
	bunch	3.68±0.15^{a}	5.01±0.04^{b}	5.06±0.34^{b}
Zn	pomace	18.48±0.92^{a}	37.59±2.33^{b}	23.14±0.53^{c}
	stems	17.50±0.33^{a}	43.55±1.11^{b}	37.54±3.66^{c}
	bunch	5.83±0.07^{a}	5.50±0.38^{a}	16.44±0.18^{b}

Values followed by different letters within a row are significant at the level 0.05.

The situation with microelemet profile of grape by-products from Austria was completely different (Table 2.). The Austrian GP, as well as GS had significantly different ($P<0.05$) Cu and Fe content, while the bunch samples differed significantly ($P<0.05$) only in Fe content. From pomace samples, GV was characterised with the lowest concentration of all the microelements, PB had the highest Fe and Zn content and for ZW the highest amount of Cu and Mn was detected. Stem from GV had the lowest Mn and highest Cu and Fe content, while the concentration of these microelement was exactly the opposite for ZW. In addition, ZW had the lowest Zn content. The highest Zn content was measured for PB. Bunches from GV and ZW had practically identical Cu concentration, the highest amount of this microelement was detected for PB. This variety had also the highest Fe content. Bunch from GV was characterised by the highest Mn and Zn concentration. The lowest amount of Zn was detected for ZW. The most Austrian bunches were also characterized by the lowest content of studied microelements.

Table 2. Microelemet profile of grape by-products from Austria (mg.kg^{-1})

		Green Veltliner	Pinot Blanc	Zweigelt
		Mean±Standard Deviation		
Cu	pomace	17.79±0.78^{a}	35.28±0.15^{b}	60.53±0.72^{c}
	stems	29.41±1.19^{a}	38.82±0.22^{b}	44.12±0.79^{c}
	bunch	13.31±0.11^{a}	18.63±0.11^{b}	13.36±0.08^{a}
Fe	pomace	42.37±2.88^{a}	95.49±3.06^{b}	70.45±1.37^{c}
	stems	42.86±1.27^{a}	103.04±0.19^{b}	229.21±2.16^{c}
	bunch	60.66±0.73^{a}	74.76±0.51^{b}	34.03±0.08^{c}
Mn	pomace	7.11±0.22^{a}	7.89±0.05^{a}	13.89±0.67^{c}
	stems	24.43±0.24^{a}	23.92±0.75^{a}	21.02±0.22^{b}
	bunch	6.33±0.13^{a}	4.10±0.25^{bc}	3.98±0.00^{c}

	stems	24.67±0.53^{a}	36.26±0.73^{b}	23.13±1.84^{a}
	bunch	61.94±3.39^{a}	16.72±0.64^{b}	12.56±0.75^{b}

Values followed by different letters within a row are significant at the level 0.05.

The total comparison of microelement profile of grape by-products from Slovakia and Austria is shown in Table 3. The GP samples from Slovakia and Austria had significantly different ($P<0.05$) content of all the studied microelements, except for Zn. In the case of GS significant differences (P<0.05) for Cu and Mn concentrations were found. The GB from two counties significantly differed (P<0.05) in Cu, Fe and Zn content.

Table 3. Comparison of microelement profile of grape by-products from Slovakia and Austria

		Slovakia	Austria	Significance
		Mean±Standard Deviation (mg.kg^{-1})		
Cu	pomace	21.08±3.76	37.87±18.62	0.017

	bunch	9.26±5.39	30.41±23.78	0.019

The level of significance was set at P<0.05.

The mineral profile of GP is well documented in the literature. Ziarati et al. (2017) revealed high trace elements content in 5 different GP from South Iran with significant differences between the cultivars. Bennemann et al. (2016) studied the mineral content of 9 GP from Brasil, also with significant differences between the varieties. These authors also declare an interesting amount of Cu, Mn and Fe in GP. Chikwanha et al. (2018) state, that GP can be a good source of Cu and Fe for animals. In comparison with Ordonez et al. (2015) higher concentration of Cu in GP was detected, however Ziarati et al. (2017) and Bennemann et al. (2017) reported much higher amount of this trace element in GP (49.87 mg.kg^{-1} and 89.24 mg.kg^{-1} respectively). Results obtained for Fe in GP are lower than reported by Ziarati et al. (2017), Bennemann et al. (2017), Ordonez et al. (2015), Wadhwa el al. (2015), Ribeiro et al. (2015) and Corbin et al. (2015). According to Ziarati et al. (2017) and Ordonez et al. (2015) higher Mn content in pomaces was detected (3.10 mg.kg^{-1} and 11.5 mg.kg^{-1} respectively), but lower than published by Ribeiro et al. (2015) and Bennemann et al. (2017) (31.21 mg.kg^{-1} and 25.43 mg.kg^{-1} respectively). Wadhwa el al. (2015) reported similar Zn concentration in GP (24 mg.kg^{-1}), while Ziarati et al. (2017), Ordonez et al. (2015) and Corbin et al. (2015) found higher (42.73 mg.kg^{-1}, 30.60 mg.kg^{-1}, 31.56 mg.kg^{-1} respectively) and Bennemann et al. (2017) lower (10.04 mg.kg^{-1}) amount of this microelement in GP. Recently, only a limited number of papers has been published on the content of microelements in GS and GB. Spigno et al. (2013) studied the mineral composition of 6 GS from Italy and found significant differences in Zn, Fe and Cu content between the cultivars. According to Spigno et al. (2013) lower amount of Cu and higher concentration of Fe and Zn was detected in GS. A justification for this difference between the mineral content of grape-by products would be the difference in the composition of the soil and climate of the growing regions. Elements such as the soil and weather factors, especially temperature, humidity and solar radiation, exert great influence on the development, production and grape quality Bennemann et al. (2016).

Conclusion

The aim of this study was to determine the microelements content of GP, GS and GB of three different cultivars of *Vitis vinifera sp*. from two countries as a possible sources for animal nutrition. Significant differences (P<0.05) in mineral composition of analyzed samples were found between the countries, as well as between the cultivars within countries. Despite the different composition of the by-products of grape processing from both countries, some similarities can be seen in the mineral profile of the same cultivars. For example, both Slovakian and Austrian GP and GS from PB had the highest Zn content and the bunches of this variety also had the highest Cu and Fe concentration. Pomaces form GV were the richest in Mn and Zn content, and ZW pomaces were characterized by the highest amount of Mn for both countries. Overall, it can be concluded that the pomaces from Slovakia were richer in the content of Fe and Mn, the stems from this country had a higher content of Zn and Mn but the bunches from Austria were characterized by a higher content of all monitored microelements. These results indicate a significant impact of the grape variety and location on the mineral profile of grape by-products.

Abstract

The aim of this study was to analyse the haplotype structure of Slovak Pinzgau cattle genome to identify and describe most frequent haplotype blocks reflecting the effect of selection in particular genomic regions. The high-density genomic data of 150 animals (BovineSNP50 BeadChip v2), covering nucleus of Slovak Pinzgau breed, were used to call haplotypes. After quality control of the data, the database included information of 41,068 SNP markers covering 2.50 Mb of the cattle genome. The average SNP spacing was 48.86±42.97 kb. The coordinates of haplotype blocks were generated from the phased SNP data based on the non-overlapping sliding windows of ten markers. The analysis indicated totally 4097 haplotype blocks with coverage rates of autosomal genome 44.82%. The majority part of blocks was concentrated on BTA1, BTA2 and BTA6. The longest haplotype block located on BTA12 (70.18 Mb – 76.95 Mb) included overall of 95 protein-coding genes. The shortest block was found on BTA14 (66.72 Mb – 68.80 Mb). To describe the most frequent haplotypes in Slovak Pinzgau genome, the frequency of each haplotype in blocks was plotted against the start position. From the identified haplotypes overall of 131 segments reached the frequency higher than 50%. Of these, two haplotypes on BTA3 (79.76 Mb – 80.47 Mb) and BTA6 (86.31 Mb – 87.53 Mb) were identified in more than 95% of animals. Inside these two regions several genes responsible for genetic control of economically important traits were detected; e.g. LEPR, CSN3, CSN2, CSN1S1. The beneficial effects of these haplotypes could be used to enhance genetic gain trough selection of animals with specific haplotypes depending on farmer's requirements.

Keywords: *autozygosity, cattle, genotyping data, selection signatures.*

Introduction

In livestock, the use of high-throughput genotyping technology allows to estimate the pattern of genetic variation at genome-wide level. The analysis of linkage disequilibrium (LD) and haplotype block structure can help to fully understand the history of the livestock populations and their genetic background (Jasielczuk *et al.*, 2016; Xu *et al.*, 2019). Various studies demonstrated that even if the linkage disequilibrium tends to decrease over larger genomic distances the complete LD can be observed among distant SNP loci as well. Moreover, Wall and Pritchard (2003) showed that extend of LD can differ significantly from one to another region in the genome. Such SNP loci showing strong LD are usually organized into the discrete blocks of haplotypes that are separated by possible hot spots of recombination (Veroneze *et al.*, 2013). Therefore, the understanding of haplotype block structure in genome can considerably facilitate the analysis of LD (Niu *et al.*, 2016).

Generally, the haplotype blocks are defined as long stretches of SNPs along a chromosome that have low recombination rates, which characterized by relatively few haplotypes (Luikart *et al.*, 2003). Clarifying the structure of haplotype block across genome can bring important considerations for genome-wide association (GWA) and genomic selection (GS) studies, such as the possibility of selecting a set of SNPs with the prospect of reducing the information of several SNPs into the information of a haplotype block, reducing the number of SNPs in a

coherent way, and optimizing the design of GWAS (Mokry *et al.*, 2014). Moreover, the analysis of haplotype block structure can be used to identify the genomic regions under strong selection pressure that occurred during the grading-up process of target population or breed.
The aim of this study was to evaluate the haplotype block structure in the genome of Slovak Pinzgau cattle and to identify and describe most frequent blocks arising probably due to the strong selection pressure on a given regions in the genome.

Material and methods

The genome of Slovak Pinzgau cattle represented genomic information of overall 152 animals (37 sires, 115 dams of sires) that were genotyped for 54609 SNPs using Illumina BovineSNP50 BeadChip v2 in commercial lab. Animals for genotyping were selected based on the pedigree analysis in order to select the sample representing the gene pool of Slovak Pinzgau cattle.
Before the scan of haplotype block structure, the genomic data were subjected to quality control (QC) using PLINK 1.9 software (Chang *et al.*, 2015). Only autosomal loci with known chromosomal position, call rate >90 % and minor allele frequency >1 % across samples were retained in dataset. All of animals with more than 10 % of missing data were filtered out. After QC the dataset consisted of 150 animals and 41,068 SNP loci covering 2.50 Mb of the autosomal genome, with average SNP spacing 48.86±42.97 kb.
To call haplotypes and identify haplotypes block structure across the autosomal genome phased genotypes were used. The initial haplotypes were determined by using SHAPEIT software version v2 (O’Connell *et al.*, 2014) based on default options. The R package GHap (Utsunomiya *et al.*, 2016) was then used to infer the haplotype blocks. The coordinates of each block across autosomes were generated based on the non-overlapping sliding windows of 10 SNP markers, following Mészáros *et al.* (2019). To identify the genomic region under strong selection pressure the frequency of haplotypes was plotted against the starting position. The selection signatures were defined based on the haplotypes with frequency higher than 50 % in the entire sample (Fig. 2). Each of region were examined in detail using the web based tool Biomart from Ensembl database (https://www.ensembl.org/).

Results and discussion

The applied QC of data resulted in final database that included 41,068 SNPs covering 2.50 Mb of the genome. The obtained average spacing among adjacent SNPs (48.86±42.97) was in accordance with previous studies in cattle (Mancini *et al.*, 2014; Randhawa *et al.*, 2016; Kukučková *et al.*, 2017). Subsequent analysis of haplotype blocks coordinates derived from phased data was based on the non-overlapping sliding windows of ten markers. The results revealed overall 4097 haplotype blocs with average size 0.55±0.24 Mb that covered 44.82 % of autosomal genome expressed by SNPs on the genotyping array. The majority part of blocks was concentrated within the autosomes BTA1, BTA2 and BTA6 (Fig. 1). The longest haplotype block located on BTA12 (70.18 Mb – 76.95 Mb) included overall of 95 protein-coding genes. The shortest block was found on BTA14 (66.72 Mb – 68.80 Mb).

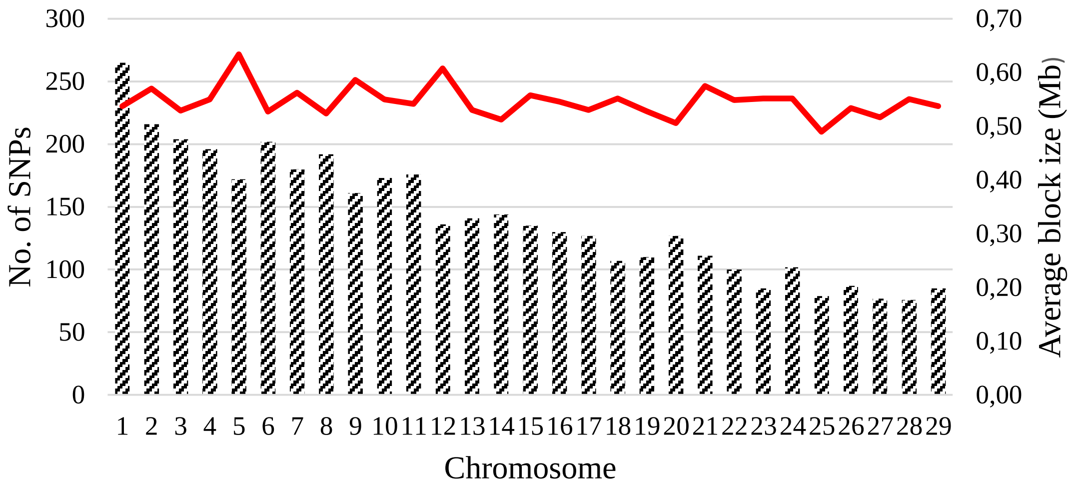

Figure 1. Distribution of haplotype blocks across autosomal genome of Slovak Pinzgau cattle

Assuming that the most frequent haplotypes in the genome of Slovak Pinzgau cattle resulted from the selective breeding for traits of interest, the haplotypes with proportion higher than 50 % in the entire sample were recognized as signals of selection. To visualize most significant genomic regions the frequency of haplotypes was plotted against the starting position (Fig. 2). From the identified haplotypes in total of 131 segments showed the proportion higher than 50 %. Top ten signals of selection are described in table 1. Of these, two haplotypes on BTA3 (79.76 Mb – 80.47 Mb) and BTA6 (86.31 Mb – 87.53 Mb) were identified in more than 95% of animals. Inside explored regions various protein-coding genes was identified (Tab. 1).

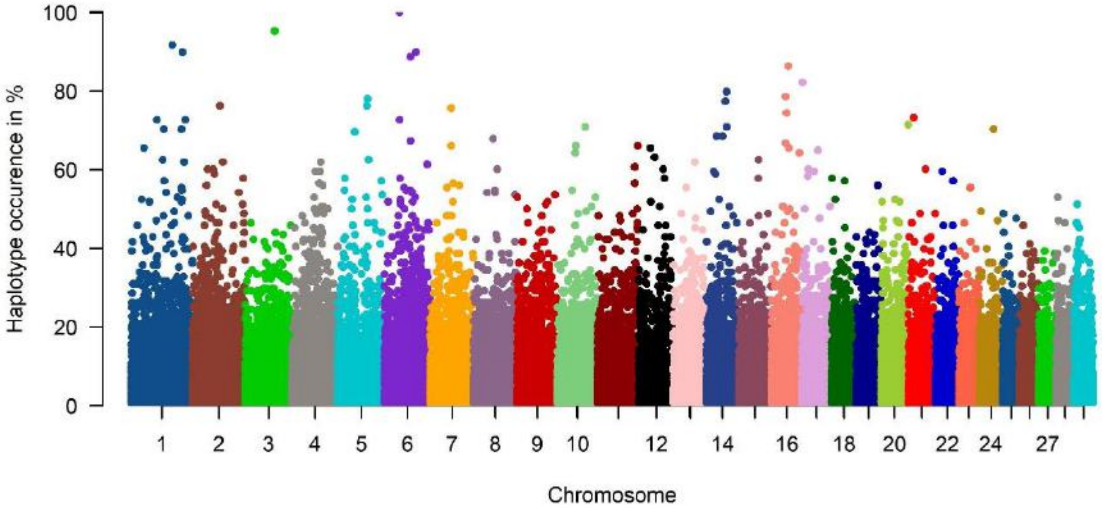

Figure 2. Genome-wide distribution of haplotypes in Slovak Pinzgau cattle

Table 1. Ten most frequent haplotypes in the analysed population

BTA	Start position (Mb)	End position (Mb)	Allele	Freq. (%)	Protein-coding genes
6	38689886	39172862	TTACGCCCCC	100.00	-
3	76481717	76797698	TAGCCGACTG	95.24	DEPDC1, LEPR
1	105134888	105477614	AATTGGACCA	91.67	LOC100141216
1	131533041	131865531	CCGGGCTTGG	89.88	TRNAG-CCC

6	81368675	82078166	AGGCTTCATG	89.88	EPHA5, CSN1, CSN2, CSN3
6	66991502	67239769	CCAGAATGAG	88.69	SLAIN2, SLC10A4, ZAR1, FRYL
16	43847822	44459269	CACTTCCCGA	86.31	PIK3CD, TMEM201, SLC25A33, SPSB1, MIR34A, GPR157, CA6
17	761685	1261843	GGGCTGGCCT	82.14	LOC617123, LOC101903170, LOC112442105
14	53246073	53532230	AACTGTTACC	79.76	TRNAE-UUC, LOC112449580, TRNAC-ACA
16	37151009	37391539	TCCCCTGCGT	78.57	F5, SELP, SELL, SELE

In the detected region on BTA1 the TRNAG-CCC gene is located. Santana *et al.* (2015) suggested that this gene is associated with body weight gain in Bos indicus cattle.
On the BTA3, the LEPR gene responsible for production traits in dairy and beef cattle was found. Trakovická *et al.* (2013) reported that both leptin receptor (LEPR) and leptin (LEP) genes significantly affected milk production and reproduction traits in Slovak Spotted and Slovak Pinzgau cattle. Moreover, these genes are involved in the control of feed intake and energy homeostasis via neurotransmitters such as neuropeptide Y and proopiomelanocortin (Lisa *et al.*, 2013).
On the BTA6, the casein family genes (CSN1, CSN2, CSN3) were identified. The casein and whey proteins are considered as two major protein groups in milk (Massella *et al.*, 2017). Various study showed that casein genes are very good genetic markers for marker assisted selection in cattle in order to select animals with higher genetic potential for target quality and quantity of milk (Miluchová *et al.*, 2018; Hristov *et al.*, 2018; Zhou *et al.*, 2019). Among other genes located within identified regions on BTA6, it was showed that the ZAR1 gene play a role in functions of oocytes in ovarian folliculogenesis, fertilization and embryogenesis (Wu *et al.*, 2003).
Functional analysis of genes located in genomic region on BTA14 revealed that one of the most biologically important genes is the TRNAC-ACA gene. The experimental study of Medeiros de Oliveira Silva *et al.* (2017) showed that this gene is associated with rump fat thickness in Nelore cattle.
On the BTA16, the MIR34A gene was found. Slabáková *et al.* (2018) reported that MicroRNA miR-34a is recognized as a master regulator of tumor suppression in humans.

Conclusion

This study showed that the most frequent haplotypes in the genome of Slovak Pinzgau cattle are located directly or very close to the genes associated with milk and beef production traits. Thus, the identified haplotype blocks reflects mainly the selection strategy of this breed that is in Slovakia bred in dual-purpose direction. In addition, this study could be used to enhance genetic gain trough selection of animals with specific haplotypes. Currently, the analysis of haplotype block structure in the genome is considered as one of the most important steps for successful application of genomic selection in livestock populations.

Abstract

During 2017 and 2018 seasons, Superior seedless grapevines received four concentrations of boric acid (17% B) namely a1) 0.0%, a2) 0.025%, a3) 0.05% and a4) 0.1% and eight treatments from single and combined applications of Sulphur, Magnesium and Zinc. The main target of this investigation was studying the effect of spraying Sulphur, Magnesium, Zinc and Boron on some vegetative growth characters, as well as physical and chemical characters of Superior seedless grapevines. Selecting the best combination of these essential nutrients responsible for overcoming the problems of small berries and shot berries accompanied with improving yield quantitatively and qualitatively was also considered. From economical point of view, it is recommended to spray Superior grapevines with a mixture containing Sulphurat 0.1%, Magnesium Sulphurat 0.5%, chelated –Zn at 0.01% and Boric Acid at 0.05% four times before bloom, just after berry setting and at two weeks intervals for improving growth, vine nutritional status, yield and quality of the berries in addition to produce filled and low shot berry clusters. This recommendation was true under experimental and resembling conditions.

Key words: Shot Berries, Superior Grapevines, Magnesium, Zinc, Sulphur, Boron.

Introduction

The importance of grapes as agricultural crop in general and as fruit crop, in particular, is doubtless when it cultivated area and its production of fruits are concerned. It is considered the first major fruit crop all over the world (Bacha 1984 and F.A.O., 2006).

Superior grapevine cultivar is considered a prime and popular grapevine cv, successfully grown under Egypt conditions. Such cultivar ripens early sometimes in the last week of May under sandy soil conditions. In addition, it has a greater potentiality of export to foreign markets due to its early in ripening character which reduced competition. In spite of introducing numerous grapevine cvs recently to Egypt such grapevine cv is still one of the prime, main, popular and the most profitable grapevine cv.

The inferior on quality due to the highest production, the small of berries and the presence of higher shot berries in Superior grape cv represent the most important serious problems which face the production and produce unfavourable clusters from the consumer point of view. Shot berries in the clusters of such grapevine cv consider a serious defect, since they detract from eye appeal and reduce at the lower extent the production and the potential for exportation. These shot berries were produced from unfertilized flowers, unfavourable nutrient and environmental conditions (Bacha, 1984 and Chapman, 1990). These problems were produced as a result of deficiency and unbalanced use of specific essential macro and micro nutrients. Previous studies showed and emphasized the possibility of using S, Mg, Zn and B for partially solving these drawbacks.

Macronutrients especially S and Mg as well as micronutrients namely Zn and B play a key role in the nutrition of the fruit crops especially grapevines (Christensen, 1977).

Sulphur (S) is beneficial on decreasing soil pH and soil salinity and increasing the availability of most nutrients and protein biosynthesis (Nijjar , 1985 and Mengel, 1985).

Magnesium is not usually applied to grapevine as a routine matter. The quick leaching of this element applied via soil aggravates the problems of magnesium deficiency. Magnesium is vital to the production of chlorophylls because every molecule contains magnesium ion in structure. It plays an important role as activation of several enzymes involved in carbohydrate metabolism and also was associated with enhancing transport of P in plant tissues(Mengel, 1985)

Zinc plays many important regulatory roles in plant development. It activates various enzymes involved in plant metabolism, enhances the biosynthesis of some organic foods and IAA and stimulates cell division, cell enlargement, water and nutrient transport (Price et al. 1972)

The different functions of boron for fruit trees according to Stile, 1961; Edmond et al., 1964; Sister et al., 1965; Christensen, 1977; Reed 1977; Adriano, 1985; Mengel, 1985; Vanekova and Madhal, 1985; Christensen, 1986 and Cook, 1986).

The present study aimed to throw some lights on the effect of foliar application of Sulphur, Magnesium, Boron and Zinc on growth and vine nutritional status, percentage of berry setting, yield, shot berries % as well as physical and chemical properties of Superior grapes. Also, the effect of these nutrients on solving the problems of inferior quality and shot berries which reflected in facilitating the possibility of marketing such grapevine cv. to local markets are also concerned.

Materials and Methods

This study was carried out during two successive seasons on Superior seedless grapevines grown in a private vineyard located at Kaluobia Governorate where the soil is silty clay, well drained and water table not less than two meters deep. Vines are spaced at two meters (between vines) x 3 meters (between rows). The selected vines (96 vines) were chosen as uniform in vigour as possible and devoted to achieve this study. The chosen vines were pruned during the first week of January in both seasons. Cane pruning system using Y shape supporting method was followed. Vine load for all the selected vines was 66 eyes (in the basis of six fruiting canes x nine eyes plus six renewal spurs x two eyes). Surfaces irrigation system was followed. The trees were irrigated through surface irrigation system. Soil analysis was done according to the procedure that outlined according to Chapman and Pratt (1965) and Black et al., (1965)

All the chosen trees received all horticultural practices that were commonly applied in the orchard except those dealing with Boric Acid, Sulphur, Magnesium and Zinc.

This study involved 32 treatments from two factors (A & B). The first factor (A) consisted from four concentrations of boric acid. (17% B) namely a1) 0.0%, a2) 0.025%, a3) 0.05% and a4) 0.1%. While the second factor (B) contained the following eight treatments from single and combined applications of Sulphur, Magnesium and Zinc:

1- Control (vines sprayed with tap water)
2- Spraying elemental sulphur at 0.1 %.
3- Spraying magnesium sulphate at 0.5 %.
4- Spraying chelated zinc at 0.5 %.
5- Spraying elemental sulphur + magnesium sulphate at the same previous concentration.
6- Spraying elemental sulphur + chelated zinc at the same previous concentration.
7- Spraying magnesium sulphate + chelatd zinc at the same previous concentration.
8- Spraying the three fertilizers together at the same previous concentrations.

Each treatment was replicated three times, one vine per each. Therefore, 96 uniform in vigour Superior grapevines (four concentrations of boric acid x eight treatments of S, Mg and Zn x three replicates x one vine) were devoted for achieving of this investigation. Boric acid (17% B), elemental sulphur (100% S); magnesium sulphate (9.6% Mg) and chelated zinc (14% Zn)

were sprayed four times during each growing season. The first spray was conducted before bloom. The second was carried out immediately after berry set. The third and fourth sprays were established at two weeks intervals just after fruit setting. Sulphur, magnesium and zinc were applied in the sources of elemental sulphur, magnesium suphate and chelated zinc at fixed concentrations namely 0.1, 0.5 and 0.05%, respectively (according to Ahmed et al., 1991a and 1991b; Zaki, 2006 and others). Triton B as a wetting agent was applied at 0.05% to all nutrient solutions. The selected vines were sprayed with these nutrients till runoff.
The following parameters were recorded.

1. Percentage of shot berries was recorded by dividing number of small berries by the total number of berries per cluster and multiplying the product by 100.
2. Yield expressed in weight (kg.) per vine was recorded at harvesting date (first week of June) when T.S.S./ acid ratio in the berries of the check treatment reached at least 22- 24 (at the 3rd week of June in both seasons) (according to Weaver, 1976) .
3. Average cluster weight (g.).Five clusters were taken at random from the yield of each vine for determination of berry weight (g.), total soluble solids, total sugars (Lane and Eynon method, 1965) and total acidity (as g tartaric acid/ 100 ml juice, (A.O.A.C., 1995).
4. Statistical analysis: all the obtained data were tabulated and statistically analyzed using New L.S.D. at 5 % for made all comparisons among the investigated treatment means (according to Steel and Torrie, 1980 and Mead et al., 1993).

Results and Discussion

1- Growth characters:
It is obvious from the obtained data that application of boron in the form of boric acid had an announced and significant effect on growth characters of Superior grapevine. There was a gradual promotion on the three growth characters namely main shoot length, number of leaves per main shoot length with increasing concentrations of boric acid from 0.0 to 0.1%. Significant differences on these growth characters were observed among all boric acid concentration except among the two higher concentrations namely 0.05 and 0.1%. The maximum values were recorded on the vines that received four sprays of boric acid at 0.1%. Untreating the vines with boric acid gave the lowest values. Similar results were announced during the two experimental seasons.
The beneficial effects of boron on the biosynthesis and translocation of carbohydrates as well as its promotive effects on cell division and the formation of organic foods could explain its impact on stimulating growth characters (Mengel, 1985).
The stimulating effect of boron on growth characters of Superior grapevines was supported by the results of El- Sawy (2009) on Superior grapevines
2- Percentages of Mg and Zn:
It is evident from the obtained data that foliar application of boric acid at 0.025 to 0.1% four times significantly stimulated leaf content of Mg and Zn as compared to the check treatment. The promotion was associated with increasing boric acid concentrations. Increasing concentrations of boric acid from 0.05 to 0.1% had no significant promotion on the essential nutrients namely Mg and Zn. The maximum values were recorded on the vines treated four times with boric acid at 0.1%. The control vines produced the minimum values.
The effect of boron on encouraging root development and absorption of water could result in enhancing the uptake of most elements (Nijjar, 1985).
These results are in agreement with those obtained by El- Sawy (2009) on Superior grapevines. The results of Kamel (2002) who worked on Flame seedless grapevines, Ahmed and Abd El- Hameed (2003) who worked on Red Roomy grapevines and Shoeib and El- Sayed (2005) who worked on Thompson seedless grapevines, supported the present results.
3- Berry setting:

It is quite clear from the obtained data, that foliar application of boric acid at 0.025 to 0.01% significantly was accompanied with improving percentage of berry setting of Superior grapevines as compared with the check treatment. The promotion was associated with increasing concentrations. Negligible stimulation was observed among the two higher concentrations namely 0.05 and 0.1%. Using 0.1% boric acid maximized the percentage of berry setting. The untreated vines showed the minimum values.

The promoting effect of boron on berry setting was confirmed by the results of Zaki (2006) and El- Sawy (2009) on Superior grapevines, Ali (2000) and Kamel (2002) on Flame seedless grapevines and Abd El- Hameed and Abo El- Ez (2004) on Ruby seedless. The same trend was reported by Ahmed et al., 1991a and 1991b; Ahmed and El- Dawwey (1992) and El-Ashram (1993) on Red Roomy grapevines.

4- Quality of the berries:

The interaction between the four essential nutrients namely S, Mg, Zn and B had significant effect on both physical and chemical characters of the berries. Increasing concentrations of boric acid from 0.05 to 0.1% under the same S, Mg and Z treatments had no significant promotion on quality of the berries. Therefore, the best results with regard to quality of the berries were obtained when the vines received four sprays of a mixture containing sulphur at 0.1%, magnesium sulphur at 0.5, chelated –zn 0.05% and boric acid at 0.05%.

5- Yield/ vine (kg.)

It is clear from the obtained data that using sulphur, magnesium and zinc either singly or in all possible combinations was significantly favourable in improving the number of clusters in the second season of study and the yield expressed in weight (kg.) in both seasons rather than non- application.. The great increment on the yield was observed on the vines that treated with Magnesium, Zinc or Sulphur in descending order. Combined application of these nutrients was preferable than using each nutrient alone in improving the yield.

These results regarding the beneficial effect of sulphur on the yield are in agreement with those obtained by Masoud (2008) on Superior grapevines as well as El- Sayed (2001); Abd El- Hady et al., (2003) and Abd El- Motty – Elham et al., (2006) on Flame seedless grapevines.

The results of Zaki (2006) and El- Sawy (2009) on Superior grapevines, Usha and Singh (2002) on Perlette grapevines and Majer (2004) on Thompson seedless grapevines confirmed the great merits of magnesium on the yield.

Table (1) Effect of spraying single and combined application of Sulphur, Magnesium , Zinc and Boron on Berry setting % and Yield / vine (Kg.) in the leaves of Superior seedless grapevines during 2017 and 2018 seasons.

Abstract

In general, grape pomace is known as good source of nutrients with high antioxidant activity and high concentration of lignin that can affect the digestion of nutrients. However, scientific sources focused on macrominerals profile of grape by-products are scarce. Thus, the aim of the research was to compare the concentration of macrominerals in wine industry grape by-products (bunch, stem, pomace) from 3 varieties of Vitis vinifera sp. (Green Veltliner - GV, Pinot Blanc - PB, Zweigelt - ZG) from Austria (AT) and Slovakia (SK). In the samples by High Resolution Continuum Source Atomic Absorption Spectrophotometry the content of macroelements - calcium (Ca), phosphorus (P), magnesium (Mg), sodium (Na) and potassium (K) were examined. Significant ($p<0.05$) differences between the countries only in the Mg and K content in bunch were observed. However, in the stem of varieties, significant differences ($p<0.01$) in the content of all macroelements between the countries were found. Similar results in the pomace macroelements profile were observed, thus the content of all macroelements was statistically significant. Between all varieties in AT samples main significant differences in the content of Ca and Mg in the bunch, in the content of Ca, P and Na in the stem and in the concentration of every macroelement in the pomace were observed. In SK, main significant differences between every variety only in Na concentrations in the bunch and in P, Mg and Na concentrations in the stem were found.

Keywords: *grape pomace, grape bunch, grape stem, minerals.*

Introduction

Increased efforts are now being directed towards a broader revaluation of polyphenol-rich residues from wine processing for obtaining high value by-products (grape pomace, seeds, skin and polyphenols) (Brenes *et al.*, 2016). Ivanišová *et al.* (2018) found high antioxidant activity in grape samples with high content of total polyphenols. The nutritional composition of grape samples shown that it varies widely, depending on the grape variety, grape origin and the conditions of fertilization (Brenes *et al.*, 2016). Also, the nutritive value of grape by-products is determined by ratio of seeds and pulps (Guerrera-Rivas *et al.*, 2016). The mineral content of grape seeds depends on winemaking process that produce grape residues which can be important source of nutrients and essential elements (Lutterodt *et al.*, 2011). Minerals in grapes are usually classified in groups depending on their mobility in phloem. Potassium, phosphorus, sulfur, and magnesium show high mobility and are accumulated and mainly localized in the skin of the grape berry during ripening. In consequence, grape skins present higher levels than grape seeds, mainly due to their high content of potassium salts localized in grape skins, specifically in the hypodermal cells (Rogiers *et al.*, 2006). In contrast, seeds are the strongest reservoir of calcium, phosphorus, sulfur, and magnesium (Coombe 1987; Gül *et al.*, 2013; García-Lomillo *et al.*, 2014). The present study has shown that GP has moderate protein, crude fat and some minerals (potassium, calcium, phosphorus, copper, iron and sulfur) (Chikwanha *et al.* 2018). As previous studies shown, there are several factors affecting the mineral composition, thus the aim of the study was to compare the concentration of macrominerals in wine industry grape by-products (bunch, stem, pomace) from 3 varieties of Vitis vinifera sp. (Green Veltliner - GV, Pinot Blanc - PB, Zweigelt - ZG) from Austria (AT) and Slovakia (SK).

Material and Methods

Wine industry grape by-products (bunch, stem, pomace) from 3 varieties of Vitis vinifera sp. (Green Veltliner - GV, Pinot Blanc - PB, Zweigelt - ZG) from Austria (AT) and Slovakia (SK) were collected. After that, grape bunch and grape pomace and stem characterised as a result of winemaking industry after juice pressing in Laboratory of Quality and Nutritive Value of Feeds at Department of Animal Nutrition, Faculty of Agrobiology and Food Resources, Slovak University of Agriculture in Nitra were analysed. After transportation to the Laboratory of quality and nutritional value of feeds of the Department of Animal Nutrition at the Slovak University of Agriculture in Nitra were samples prepared for nutrition analysis in accordance to standard analytical laboratory methods. The contents of mineral nutrients were determined by High Resolution Continuum Source Atomic Absorption Spectrometer ANALYTIK JENA contrAA 700 (Ca, Mg, Na, K) and 6400 Spectrophotometer (P). The determination of individual element content was based on the absorptions measured at the following wavelengths: Ca content was detected at 422.7 nm, P at 666 nm, Mg at 285.2 nm, Na at 589.0 nm and K at 766.5 nm. Results were statistically evaluated with IBM SPSS v. 20.0. Descriptive statistics and statistical significance of differences between grape varieties using One-way ANOVA (Tukey test) were generated. Then, statistical significance of results between the countries using Independent samples T-test was realised.

Results and Discussion

In both countries in grape bunch the content of K was the highest (Table 1). The highest content of K in AT in PB variety and in SK in ZG variety was determined. However, significant differences ($p<0.05$) in the K content only between the GV and PB, ZG and PB variety in AT were found. In SK, significant differences between the ZG and PB, ZG and GV were observed. The second most abundant mineral in grape pomace in both countries was Ca. Moreover, significant differences between the Ca concentrations in all varieties were found ($p<0.05$). In contrary, in SK significant results only between GV and ZG were determined ($p<0.05$). Then, the variety of GV bunch had in both countries the highest content of Ca. Third highest concentration in grape bunch had P. Though, there were no significant differences in AT between the grape bunch varieties. On the other hand, in SK there were significant differences between the ZG and GV, ZG and PB variety ($p<0.05$). The highest content of Na in AT in ZG variety and in SK in GV variety was observed. But, significant differences only between PB and GV, PB and ZG in AT were found ($p<0.05$). However, in SK significant differences between the all grape bunch varieties were observed ($p<0.05$). The lowest concentrations from minerals in the case of Mg in both countries were determined. In AT grape bunch samples were Mg concentrations between the varieties different ($p<0.05$). On the other hand in SK samples, significant differences only between the GV and PB, GV and ZG were observed ($p<0.05$). Then, the highest Mg content in AT in PB variety and in SK in GV variety was found. Significant differences between the AT and SK samples only between Mg, Na and K content were found ($p<0.05$). There are few studies about the mineral content of the whole grape bunch. Thus, the mineral content of grape bunch depends on the proportion of rachis, pulps, skins and seeds in grape. Ziarati *et al*. (2017) determined mineral content consisted of pulps, seeds and peels of 5 different grapes as follows: Ca 845.6 $mg.kg^{-1}$, Mg 321.5 mg.kg^{-1}, K 1 348.6 mg.kg^{-1}, P 112.0 mg.kg-1 and Na 1.36 mg.kg^{-1}. In comparison with recent study, the content of minerals in AT and SK samples was higher. According to Arrobas *et al.* (2014) in the pulp of grape is the lowest content of minerals in grape seed, then pulp and highest in the stem. Average concentration of minerals calculated from 3 different (pulp, seed, rachis) parts in their research was K 13 100 mg.kg^{-1}, Ca 4 400 mg.kg^{-1}, P 1 500 mg.kg^{-1}, Mg 1 133 mg.kg^{-1}, that is comparable to all samples from AT and SK except of Mg content which was lower in recent study.

Abbreviatons: C - country, M - mineral, GV - Green Veltliner, PB - Pinot Blanc, ZG - Zweigelt, T - Total summary, $\bar{x}$ - mean, SD - standard deviation, AT - Austria, SK - Slovakia, Ca - Calcium, P - Phosphorus, Mg - Magnesium, Na - Natrium, K - Potassium. Different small letters in the columns indicate significant differences between the varieties at the 0.05 level (Tukey Test). Different large letters in the columns indicate significant differences between the countries at the 0.05 level (Independent Samples T-Test).

Similarly like in grape bunch, the most abundant mineral in grape stem in both countries was K (Table 2). However, in AT significant differences only between the PB and GV variety, PB and ZG variety were found ($p<0.05$). On the other side, in SK grape stem samples significant differences between the GV and PB variety and GV and ZG variety were observed ($p<0.05$). The highest K content in AT samples in ZG variety and in SK samples in PB variety was found. Then, again like in grape bunch, the second highest concentrations from minerals in the case of Ca were determined. In AT samples, significant differences between the samples were found, however, in SK samples significant differences only between PB and GV and PB and ZG were observed ($p<0.05$). Then, in AT the highest Ca concentrations in GV variety and in SK in ZG variety were monitored. The highest P concentrations in both countries in samples of ZG variety were found. Moreover, in both countries there were significant differences between the all varieties ($p<0.05$). The Mg content of grape stem samples in both countries in GV variety was the highest. However, significant differences in AT only between GV and PB and GV and ZG were observed ($p<0.05$). On the other hand in SK samples, all varieties had significant different content of Mg. Similarly like in grape bunch, the lowest content from minerals was formed from Na. Moreover, in both countries were differences between the varieties in Na concentration significant ($p<0.05$). However, in AT the highest concentrations of Mg in the ZG and in SK in the GV grape stem were found. Overall, significant differences between the AT and SK samples in the content of Ca, Mg, Na and K were observed. Nowadays, research focused on the mineral composition of grape stem is rare but several studies described concentration of minerals in the grape stem and their pattern. For example, Arrobas *et al*. (2014) found lower K content in grape stem in comparison with SK and AT samples (28 600 mg.kg^{-1}). Lower concentrations of K found also Spigno *et al.* (2013) from 25 800 to 31 700 mg.kg^{-1}, thus only GV sample in SK was in their found interval. Arrobas *et al.* (2014) observed the higher content of Ca 5900 mg.kg^{-1} in comparison with all AT samples but lower compared to all SK samples. However, Spigno *et al.* (2013) determined the Ca content in grape stem from 4 800 to 9 400 mg.kg^{-1} that was corresponding with SK samples, however concentrations of Ca in PB and ZG variety from AT were lower. The content of P in grape stem samples from AT and SK compared to Arrobas *et al.* (2014) (1 800 mg.kg^{-1}) was higher in all analysed samples. Wide range of Mg content determined Spigno *et al.* (2013) from 800 to 3 400 mg.kg^{-1} which was comparable to all samples of grape stem from AT and SK. On the other side Arrobas *et al.* (2014) observed comparatively higher content of Mg (1 400 mg.kg^{-1}) in comparison with AT samples, however the content of Mg in SK stem samples was higher. In overall is possible to detect in ash of grape stem more than 20 minerals with the major content of K, followed by Ca, Mg and Na (Prozil *et al.*, 2012).

Abbreviatons: C - country, M - mineral, GV - Green Veltliner, PB - Pinot Blanc, ZG - Zweigelt, T - Total summary, $\bar{x}$ - mean, SD - standard deviation, AT - Austria, SK - Slovakia, Ca - Calcium, P - Phosphorus, Mg - Magnesium, Na - Natrium, K - Potassium. Different small letters in the columns indicate significant differences between the varieties at the 0.05 level (Tukey Test). Different large letters in the columns indicate significant differences between the countries at the 0.05 level (Independent Samples T-Test).

In both countries the highest content in grape pomace from minerals had K in ZG variety (Table 3). While in AT samples were differences between the all varieties significant, in SK samples significant differences only between the GV and ZG were found ($p<0.05$). Then, Ca content in the both countries was also the highest in ZG variety. However, significant differences between all varieties only in AT samples were found ($p<0.05$). In SK samples were different results in the content of Ca only between ZG and GV, ZG and PB ($p<0.05$). Similar findings were also in the case of P content. The highest P concentrations in AT ale in ZG variety but in SK samples in PB variety were found. Then, significant results between the all varieties in AT samples were found ($p<0.05$). In contrary, in SK samples were significant differences only between the PB and GV, PB and ZG ($p<0.05$). Then, the highest Mg concentrations in AT and SK grape pomace samples in GV variety were found. Significant differences between the all varieties in AT samples were found, but in SK samples only between ZG and GV, ZG and PB ($p<0.05$). Finally, the lowest content from minerals formed Na. In both countries, the highest Na content in PB variety was determined. However, similarly in comparison with other minerals in AT samples, significant differences between the grape pomace varieties were observed. Differences between the grape pomace Na content from SK were significant only between the ZB and PB and ZG and GV ($p<0.05$). High variability in the concentration of K is observed between the studies. In comparison with Corbin *et al.* (2015) higher content of K in AT samples (20267 – 27333 mg.kg^{-1}) but similar in SK samples was found. Lower content of K observed Chikwanha *et al*. (2018) (15000 – 25300 mg.kg^{-1}) compared to AT samples, however in SK samples was K concentration in their found interval. Corbin *et al.* (2015) found the P concentrations from 2367 to 2733 mg.kg^{-1}. In AT samples of grape pomace, similar P content except of ZG variety was found. In contrary, compared to SK samples lower K content in their research was observed. Chikwanha *et al.* (2018) determined the maximal P concentration in grape pomace 3420 mg.kg^{-1}, which was higher compared to AT and SK analysed samples except of PB variety in SK. In comparison with Bennemann *et al.* (2016), the P content in the grape pomace was higher in all analysed samples from both countries (330.5 – 497.6 mg.kg^{-1}). Similar concentration of Ca found Corbin et al. (2015) (2170 mg.kg^{-1} – 3867 mg.kg^{-1}) compared to AT samples. However, in SK grape pomace samples higher content of P except of GV variety was determined. Chikwanha *et al.* (2018) found also similar concentration of Ca in grape pomace compared to AT samples but also lower in comparison with SK samples (2290 – 3730 mg.kg^{-1}). In contrary, Botelho *et al.* (2018) observed almost the same level of Ca compared to both countries except of ZG variety from SK (1580 – 4295 mg.kg^{-1}). Chiwkanha *et al.* (2018) observed higher Mg content (950 – 1370 mg.kg^{-1}) compared to AT samples, however SK samples were in their found interval. On the other side, Bennemann *et al.* (2016) determined in grape pomace similar Mg content from 587.3 to 1547 mg.kg^{-1}. Then, Corbin et al. (2015) found the content of Mg similar to AT samples (710 – 987 mg.kg^{-1}). Lower content of Na compared to SK and AT samples found Corbin et al. (2015) from 58 to 61 mg.kg^{-1}. On the other side, Chikwanha *et al.* (2018) observed similar Na content in grape pomace except of GV and PB varieties from SK (328 – 1210 mg.kg^{-1}).

Different large letters in the columns indicate significant differences between the countries at the 0.05 level (Independent Samples T-Test).

Conclusions

The overall concentration of minerals in both countries is the highest in the stem, then pomace and the lowest in grape bunch. However, larger differences between the countries are in the mineral content of grape bunch and pomace. Also, proportion of minerals in grape products is affected by variety and their origin. But the same concentrations patterns are observed in all by-products, thus there is the major content of K, then Ca, P, Na and the lowest content of Mg. However, it is necessary to realise further analysis focused on the mineral content of grape by-products because of lack information about this problematic in recent science.

Ackonwledgments

This work was supported by the Slovak Research and Development Agency under the contract no. APVV-16-0170 (By-products from grape processing as an bioactive substance source in animal nutrition).

Abstract

The native breeds of pigs are those that grow in a certain region and / or country as local, autochthonous breeds. In Poland there are 3 breeds: Pulawska, Zlotnicka White and Zlotnicka Spotted pigs. The aim of work was to analyse the meat quality of Polish native breed of pigs. We performed chemical analysis of obtained samples as well as colour, shear force and thermal loss analysis. Highest fat content (%) were found in Zlotnicka Spotted while the lowest in Zlotnicka White. Highest L* value and thermal loss were found in Pulawska breed. Highest shear force value were found in Zlotnicka White and differ significantly compared to other breeds. The meat of Pulawska breed, produced for project BIOSTRATEG was characterized by better quality parameters in comparison to meat of fatteners of the same breed bought in a popular shop-network. The meat of Pulawska, Zlotnicka White and Spotted pigs is a good quality raw material which is used for production of traditional and regional meat products gaining high sensory scores and good recognition among consumers. Promotion of traditional products obtained from above breeds will favour the development of their breeding.

Key words: *fatteners, native pig breeds, meat, quality*

Introduction

The domestic animals' breeds accompany human more than 10 thousand years. They have given not only food but also helped with field work, were the components of agri-landscape playing the immanent part of nature, of culture and even ethnography (Litwińczuk, 2017). Nowadays, in Poland according to data obtained for 2016, the altogether number of registered and preserved with special *in situ* programs, is 83 breeds, varieties and lines, where 43 are mammals, 35 domestic birds and 5 bees lines. They are breed in 3259 farms (Krupiński *et al.*, 2017). The native breeds of pigs are these, which are grown up in the certain region and/or country for example, Mangalica, Moravka, **Resavka,** Iberian, Casertana, Alentejana, Bazna, Mora Romagnola, Krskopolje, Turopolje. In Poland as native breeds there are 3 breeds: Pulawska, Zlotnicka White and Zlotnicka Spotted pigs (Szyndler-Nędza *et al.*, 2011). These breeds are characterized by worse fattening, slaughter and traits but their advantages are good quality raw meat, lower feeding demands, natural resistance for worse environmental conditions and higher resistance against illnesses and stress in comparison to commercial breeds. They are outstanding for high reproduction traits and well adaptation in difficult environmental conditions (Krupiński *et al.*, 2017). Also they are known for good maternal traits (Szyndler-Nędza *et al.*, 2011). The pigs of Polish native breeds can be used for breeding of heavy fatteners, because even afterwards obtaining of high body weight the meat shows the very good quality (Babicz *et al.*, 2009; Martyniuk, 2010; Szyndler-Nędza, 2012; Cebulska, 2015). The meat of these breeds can be characterized by advantageous muscle fibres structure and the amount of intramuscular fat favourably influencing the meat marbling and sensory properties. Thanks to above the meat of these pigs breeds is used for production of regional meat products (Florowski *et al.* 2006; Blicharski, 2007; Szyndler – Nędza *et al.* 2011). In 1996, the Pulawska, Zlotnicka White and Zlotnicka Spotted pigs were included in Genetic Resources Conservation Programme in order to preserve biodiversity and in 2010 Polish Pig Breeders and Producers Association POLSUS cooperation with the Auchan hipermarket network was launched, which in their offer included the meat of Puławska breed pigs

The aim of work was to analyse the meat quality of Polish homeland traditionally breed pigs.

Material and methods

In scope of the project *"The uses and the conservation of farm animal genetic resources under sustainable development"* co-financed by the National Centre for Research and Development within the framework of the strategic R&D programme "Environment, agriculture and forestry" – BIOSTRATEG, contract number: BIOSTRATEG2/297267/14/NCBR/2016 were analysed meats of native Polish pigs' breeds. The fatteners of Polish native breeds were obtained from farms specially dedicated for this type of breeding-these were namely: Pulawska, Zlotnicka White and Zlotnicka Spotted. The fatteners with weight from about 120 to 130 kg were slaughtered in professional slaughter-houses. The experimental material was pork loin (*m. longissimus dorsi*) obtained from 10 purebreed fatteners (5 gilts and 5 barrows).

Also there were analysed loins (*m.longissimus dorsi*) and hams (*m. semimembranosus)* of 6 Pulawska breed pigs' meat bought in shop-network delivering meat of fatteners specially breed for the BIOSTRATEG project. The obtained samples of meat were minced and subjected to physico-chemical analyses in laboratory of Department of Animal Product Technology University of Agriculture in Kraków. In the raw meat samples:

• water content according to the standard *PN-ISO 1442:2000*,
• fat content according to the standard *PN-ISO 1444:2000*,
• protein content by Kjeldahl method *(PN-75/A-04018)*,
• total ash content according to the standard *PN-ISO 936:2000*,
• total carbohydrates content was calculated assuming that the all total solids and water stand for 100%

To analyse meat weight cooking loss samples were heated to reach the internal temperature of 75ºC in the geometric centre of the sample. The results were computed from the difference between the weight before and after cooking,

• the measurements of colour of meat samples were obtained using CIELab system. Lightness [L*], redness [a*] and yellowness [b*] of meat were determined using a Konica Minolta CM – 600d spectrophotometer, for the D65 illuminant and a 10° standard observer,
• the pH of the muscle was measured with the use of pH-meter Benchtop Electrochemistry Meter (Belgium).
• The measurement of shear force was performed with Warner-Bratzler triangle edge knife. From each lot were cut out 5 cylindrical samples (diameter 14mm , height 15mm) and the force needed for rectangular samples cutting was measured. The test blade speed was 2mm/s.

Statistical analysis

All samples were obtained at least in duplicates. All results were analysed with ANOVA and present as means with standard deviation. The calculations were performed with Statistica 6.0 *(StatSoft, 2003)*.

Results and discussion

In Table 1 is presented the chemical composition of meat loin of fatteners. The content of protein in the loin of native pigs ranged from 22.10% (Zlotnicka Spotted breed) to 23,51% (Zlotnicka White). Szulc and Skrzypczak (2016) analysed chemical composition of muscle *longissimus dorsi* of different pigs breeds show that protein content in Zlotnicka Spotted breed meat ranges from 22.3% to 24.54%, and in Pulawska breed meat from 22.0 to 23.37%. The intramuscular fat (IMF) level in Zlotnicka White loin was 2.51% whereas in Zlotnicka Spotted 3.40%. Szulc and Skrzypczak (2016) reported that IMF content in *longissimus dorsi* of Zlotnicka Spotted breed ranges from 1.87 to 3.44%, whereas in Pulawska *longissimus dorsi* meat from 2.20 to 3.70%. Although the high intermuscular fat content has advantages influence on flavor and texture of meat, but consumers may not accept IMF content Wood *et al.*, (1999), Daszkiewicz *et al.*, (2005) and Tyra and Mitka (2015) reported that the optimum taste, tenderness and juiciness show the meat with fat content ranging from 2.5 to 3.0%. The lower amounts (1,19 ÷ 2,20%) of intramuscular fat and paralely lower energy value of loins of Pulawska pigs was obtained by Piórkowska *et al.* (2010) and Kasprzyk *et al.* (2013). Above described differences arised from different ways of feeding and breeding conditions of Pulawska breed pigs, in compared assessments. The ash content in meat of analysed fatteners was similar and did not differ statistically.

In Table 2 are presented selected quality traits of analysed breeds. pH24 value was similar to results obtained by other authors Szulc and Skrzypczak (2015, 2016). The meat of Pulawska breed pigs was characterized by higher values of parameter L* (56.73) the higher values of parameter a* (9.79) (was more red). The lighter colour and the higher value of parameter L* were, the most probably, the effect of higher fat content; the higher contents of fat make the meat brighter. Szulc and Skrzypczak (2016) revealed that the meat of native breeds is characterized by the lightness value L* at level 45-50. They also mentioned that the differences in intermuscular fat content influence on muscles , the results of colour measurements so then on lightness and share of red colour. Szulc *et al.* (2012) reported the low share for red colour (4.06) whereas Jankowiak *et al.* (2010) and Bocian *et al.* (2012) found the bigger shares of red colour (16.82–17.34) in meat of Zlotnicka Spotted pigs' breed. After the thermal treatment (roasting), there were obtained, in meats of both fatteners groups, similar thermal lossess, although in loins of Pulawska breed these losses were observed as lower but that difference was not statistically significant.

Table 1. Chemical composition of loins of native breeds of fatteners

Component	Fattener's breed		
	Pulawska	Zlotnicka White	Zlotnicka Spotted
Water	72.37±2.72	72.60±0.89	72.70±0.75
Total solids	27.63±0.78	27.40±0.86	27.30±0.72
Protein	23.02±5.55	23.51^{a}±3.97	22.10^{b}±3.52
Fat	3.10±0.49	2.51^{a}±0.84	3.40^{b}±0.64
Ash	1.10±0.07	1.08±0.09	1.20±0.13
Carbohydrates	0.41±0.01	0.30±0.02	0.60±0.04

Mean values in rows marked with a different letters differ statistically significantly at $p \leq 0.05$

Szulc and Skrzypczak (2016) revealed that the thermal loss for local pigs' breeds is slow. But Wojtysiak and Pawłowicz (2014) obtained, the comparable to ours, thermal loss for Pulawska breed pigs' meat 35.92 %. Roasted meat of Zlotnicka Spotted breed was characterized by a smaller shear force than meat of Zlotnicka White and Pulawska pig's breeds.

Table 2. Selected quality characteristics of loins of analysed breeds.

Parameters	Fatteners breeds		
	Pulawska	Zlotnicka White	Zlotnicka Spotted
pH_{24}	5.60±0.03	5.58±0.03	5.52±0.02
Colour parameters			
L*	56.73^{a}±4.71	50.74^{ab}±3.89	46.43^{b}±4.03
a*	9.79^{a}±1.77	5.03^{b}±1.08	8.20^{a}±0.92
b*	8.65^{a}±1.57	3.87^{b}±0.56	2.95^{b} ±0.44
Thermal losses %	32.88^{ab}±2.98	34.16^{a}±3.86	29.32^{b}±3.17
Shear force of roasted meat [N]	18.16^{a}± 3.01	22.63^{b}± 3.41	17.06^{a}± 2.59

Mean values in rows marked with a different letters differ statistically significantly at p≤0.05

In Table 3 are presented chemical composition and selected quality characteristic of loin and ham of Pulawska breed bought in shop-network and produced for BIOSTRATEG project. The meat of Pulawska pigs, bought in the shop, was characterized by bigger thermal loss and higher shear force in comparison to meat of pigs breed in used for BIOSTRATEG project. The meat bought in the shop was originated from fatteners with high meatness (lower fat content), and the high thermal loss points for crossbreed with Pietrain breed. Janiszewski *et al.* (2015) assessed the quality of meat and of whole carcasses of Zlotnicka Spotted breed and of its crossbreeds with PLW (Polish Large White) and Duroc. The crossbreeding of Zlotnicka breed pigs with PLW and Duroc caused growth of meat content in the carcass and lowering of lard amounts. Florowski *et al.* (2016) found that the pig's breed is the significantly differing factor for many meat characteristics.

Table 3. Chemical composition and selected quality traits of loins and hams of Pulawska breed pig.

Parameters	Muscles			
	Loin – (*m. longissimus dorsi*)		Ham (*m. semimembranosus*)

Among all pig's breeds present in Poland the most valuable meat (better sensory scores) is in Duroc and native breeds (here belongs Pulawska), whereas less valuable is meat obtained from Pietrain breed. With lowering of fat content in fatteners the lossess of preservation and preparation for consumption of meat are growing (Trombetta *et al.*,1997).

Conclusions

The meat of Pulawska, Zlotnicka White and Spotted breeds of pigs is a good quality raw material which is used for production of traditional and regional meat products gaining high sensory scores and good recognition among consumers. The meat of Zlotnicka Spotted breed deserves the special attention because of advantages intramuscular fat content, lower thermal losses and smaller shear force. The meat of Pulawska breed, produced for project BIOSTRATEG was characterized by better quality parameters in comparison to meat of fatteners of the same breed bought in a popular shop-network. In order for meat from the Pulawska porkers sold in the shop network to compete for meat of very fine meat fatteners, it is necessary to change the requirements for porkers of the Pulawska breed and eliminate the crossing of the Pulawska breed with pietrain boars. Promotion of traditional products obtained from above assessed breeds will favour the development of their breeding and stocks rising.

Abstract

The aim of this study was to determine the lactation stage effect on the concentration of selected essential and toxic elements in the sheep milk from area of Slovakia with slightly disturbed environment and to find the actual contamination of selected areas, in view of its environmental character, and to refer to the suitability of the use of milk from this area to other food processing. The research was conducted with 300 sheep (Tsigai breed), average age of 6 years, where the milk samples were taken during the spring season (early lactation stage), summer season (middle lactation stage), and autumn season (late lactation stage). Sheep were reared on the extensive pastures, reared indoors afterwards, fed with pasture *ad libidum*. Milk samples were collected after morning and afternoon milking. Despite the fact that there was large number of animals on the farms, average milk samples were obtained from milk tanks at the end of milking. The samples of milk were analyzed by atomic absorption spectroscopy and atomic emission spectrometry. Significant increase ($P<0.05$) of Ca, Mg, Se and Fe concentrations were found in the milk during the lactation. In case of Mg, Se and Fe increase of concentration was found only in the last stage of lactation. Statistically significant difference ($P<0.05$) in concentration of Zn were found during the lactation stages, but the concentration of Zn decreased between the spring and summer lactation and increased between the summer and autumn lactation. Concentration of essential element (Cu) and toxic elements (As, Cd, Hg, Ni, Pb) in milk was low, below the LOQ. It can be concluded, that the use of milk of sheep from this area for direct use or for dairy products processing is appropriate, safe and poses no health risk for the consumers.

Keywords: *sheep, milk, environmental burden, essential elements, toxic elements, lactation stage.*

Introduction

Milk and dairy products are important components of the human diet. Milk has been described as a complete food because it contains vital nutrients including proteins, essential fatty acids, lactose, vitamins and mineral in balanced proportions. However, milk and products of milk can also contain chemical hazards and contaminants, which constitute a technological risk factor for dairy products, for the related commercial image and, above all, for the health of the consumer (Licata et al., 2004).
The importance of milk in human diet is widely established and its regular consumption is recommended, especially for young children. In recent decades sheep milk has assumed an increasingly important role in the human diet, not just for infants but also for adults and especially nursing mothers (Sanz Ceballos et al., 2009; Kapila et al., 2013)
Sheep milk may contain various elements of nutritional or toxicological importance, and their levels can vary according to intrinsic factors (lactation stage, animal species and health status), and extrinsic factors (season, feeding and environment). Because the nutritional habit of these small ruminants to graze plants and grass, they may be considered such

environmental bio-indicators and their milk a good matrix to monitor the pollution status. Heavy metals such as arsenic, cadmium, lead, nickel and mercury whose toxicity is well known (Llobet et al., 2003), are widely dispersed in the environment and their contamination sources are various: grazing animals are exposed to their accumulation by ingestion of water, grass and feed (Hilali et al., 2011; Rahimi, 2013; Najarnezhadand and Akbarabadi, 2013).
Toxic heavy metals such as lead (Pb), cadmium (Cd), mercury (Hg) and nickel (Ni) have negative effects on livestock health (Lane et al., 2015), as well as harmful effects on human health (Perween, 2015). This problem is more important for children, who consume large amounts of milk and are the most vulnerable population. Pb and Cd are not essential for animals and plants. These metals are potentially toxic, causing hematologic, neurotoxic, and nephrotoxic effects even at low concentrations. Human exposure to these heavy metals has a negative effect on specific organs that may lead to metabolic disorders, fatigue, heart failure, and cancer. Furthermore, both chronic and acute exposure to Pb can result in encephalopathy (vomiting, depressed consciousness and lethargy), and it also decreases the learning ability in childhood (JECFA, 2011; EFSA, 2012).
Micronutrient elements such as iron, copper and zinc are essential for many biological functions. Deficiencies of such elements contribute significantly to the global burden of disease; however, if present at higher levels, they can have a negative effect on human health. Both toxicity and necessity vary from element to element. Milk and milk products are considered very poor sources of iron and copper and can supply smaller quantities of zinc (Kazi et al., 2009).
Thus, the aim of the study was to determine by monitoring of environment the content of essential elements (Ca, Mg, Fe, Se, Cu, Zn) and toxic elements (Cd, As, Pb, Hg, Ni) in milk from selected farm of Slovakia according to different stages of lactation. To find the actual contamination of selected area to refer to the suitability or unsuitability of the use of milk from these areas, to other food processing.

Material and Methods

The monitoring of area was realized during the lactation stages on selected farm of Slovakia. According to the Ministry of Environment of Slovak Republic (SR) and Slovak Environmental Agency, regions of SR are divided into the three types of environmental quality: 1st environmental quality – regions with undisturbed environment and convenient environment; 2nd environmental quality – regions with a slightly disturbed environment, areas with disturbed environment and areas with widely disturbed environment; 3rd environmental quality – regions with heavily disturbed environment (Bohuš and Klinda, 2008). For monitoring in this study, the village Klátova Nová Ves (Western Slovakia) which is characterized as area with widely disturbed of environment was selected. This region, also called Horná Nitra, is typical with contamination of soil by heavy metals (As, Hg). Contamination soil and environment of this region is caused by power station in Nováky, where the coal is burned. The ash from the burning of low quality coal contains high amounts of As.
The research was conducted with 300 ewes (Tsigai breed), average age of 6 years. Total number samples of milk were 15 and about 500 mL sample of milk were taken during the spring season (early lactation stage), summer season (middle lactation stage), and autumn season (late lactation stage). Sheep were reared on the extensive pastures, reared indoors afterwards, fed with pasture *ad libidum*. Milk samples were collected after morning and afternoon milking. Despite the fact that there was large number of animals on the farms, average milk samples were obtained from milk tanks at the end of milking.
Milk samples for determination of Ca, Zn, Fe, Mg, Cu, Ni, Pb, Cd were prepared by mineralization with microwave decomposition with HNO3 and H2O2 (microwave oven

MARS 6 240/50). Milk sample for determination of Se was prepared by mineralization with microwave oven with HNO3 and H2O2 (microwave oven MARS 6 240/50), removal nitrous gases, cooling, followed addition solution of HCl, reduction from Se6+ to Se4+ by heated at 90°C. Milk samples for determination of As were prepared by dry mineralization with oxidation mixture (oxygen, oxides of nitrogen, ozone), heated at 300 – 400°C. The ash was re-diluted in solution of HCl. As and Se in milk were analyzed using the hydride generation atomic absorption spectroscopy (HG-AAS) method with Spectr AA-220 FS (The Netherlands). Ca, Fe and Mg in milk and feed were detected using the inductively coupled plasma-atomic emission spectrometry (ICP-AES, Varian 720-ES, USA). Cd, Pb and Ni in milk and feed were analyzed using the electro thermal atomization atomic-absorption spectrometry (ETA-AAS, Agilent DUO AA 240Z/240FS, USA). Zn and Cu in milk and feed were analyzed using the (F-AAS, DUO AA 240Z/240FS, USA). Hg in milk and feed was analyzed using the Advanced Mercury Analyzer and atomic-absorption spectrometry (AMA-AAS, Altec CR) without the need for chemical preparation of the sample. All analyses were conducted in certified testing laboratory Eurofins/Bel Novamann (Nové Zámky, Slovak Republic).

Data were analyzed with statistical software IBM SPSS Statistics 20. The results are presented as arithmetic mean with standard deviation and maximum and minimum value of concentrations of selected metals. Means of concentrations of metals during the lactation stages were compared using Tukey HSD test and differences between lactation stage effect declared significant at $p<0.05$ level.

Results and Discussion

The average concentrations of elements in feed and sheep´s milk as well as other statistical measurements were determined (Table 1 and Table 2). During the spring season content of essential elements in feed (Ca, Zn, Fe, Mg, Cu) and toxic metals (As, Cd, Hg, Ni, Pb) was higher than during the autumns season. In case of autumn season, content Se and all analyzed toxic metals was below the LOQ (limit quantification). Bushra et al. (2014**)** studied concentrations of toxic elements in feed from rural and urban areas. They found, that the content of Cd, Ni and Pb was 0.27, 1.68, 4.11 mg.kg-1 in urban areas and in rural areas 0.037, 0.024, 4.52 mg.kg-1, respectively. Compared to results of their study, on farm of Klátova Nova Ves (widely disturbed environment), content of Pb and Cd was lower and content of Ni was higher. Lower content of Ni, As, Cd, Pb in feed state Zhou et al. (2017) compared to results of this study.

Animal studies demonstrate that nickel has negative effects on the structure and function of the testis, seminal vesicles and prostate gland; there is similar report on adverse effect on spermatozoa (Pandey et al., 2000; Forgacs et al., 2001). Lukáč et al. (2014) reported the negative effect of nickel on spermatogenesis. The decrease in the relative volume of germinal epithelium indicates on alterations of the spermatozoa production. Cadmium causes tissue damage in humans and animals and many toxicological studies have found the functional and structural changes in the kidneys, liver, lungs, bones, ovaries and fetal effects (Kukner et al., 2007; Massányi et al., 2007).

Tab. 1 Concentrations of mineral and selected toxic elements in feed of sheep (mg/kg)

Green forage											
Elements	Ca	Zn	Se	Mg	Fe	Cu	As	Cd	Hg	Ni	Pb
Spring season	7400.0	42.2	0.065	3050.0	333.0	11.2	1.2	0.15	0.2	6.8	3.8
Autumn season	1140.0	5.3	<0.03*	314.0	72.0	1.6	<0.03*	<0.01*	<0.3*	<0.10*	<0.30*

*concentrations with this index are below the LOQ (limit quantification)

A positive result of this study was, that content of toxic metals, which detected in feed on farm, did not affect on their occurrence in sheep milk. Content of all toxic elements (As, Hg, Ni, Pb, Cd) in milk was below the LOQ (Table 2). The content of Pb in milk in this work was significantly lower than in milk samples from Iran (Najarnezhadand and Akbarabadi, 2013; Rahimi, 2013) and very low in comparison to the results of Anastasio et al. (2006) and Licata et al (2012).

Tab.2 Descriptive statistics for concentrations of essential and toxic elements in sheep´s milk

Element, mg/kg	Mean±SD	Min	Max
Ca	1730.00±769.61	1040.00	2560.00
Mg	151.67±54.42	89.00	187.00
Zn	4.33±3.22	2.00	8.00
Se	<0.030	-	-
Fe	0.67±0.58	0.1	1.0
Cu	<0.50	-	-
As	<0.030	-	-
Cd	<0.0040	-	-
Pb	<0.010	-	-
Ni	<0.10	-	-
Hg	<0.002	-	-

SD- standard deviation; Min- minimum value; Max- maximum value

It is evident (Table 3) that milk of sheep from farm of Klátova Nová Ves was found significant increase concentrations of Ca during the lactation and significant increase of Mg between early and middle lactation stage and significant decrease between middle and late lactation stage. Concentrations of Zn were identical during the early and middle lactation stage and in the last stage of lactation significantly decrease of Zn concentrations was recorded. Concentrations of Se were below the LOQ during the lactation stages and the highest concentration of Fe was found in middle stage of lactation. Cu and toxic elements (As, Cd, Hg, Pb, Ni) during the lactation stages were below the LOQ.

Compared to present study, Antunovič et al. (2016) in sheep´s milk in Croatia found increased concentrations Ca, Mg during the lactation and increased concentrations Fe and Se during the early and middle stage of lactation. Al-Wabel (2008) recorded in sheep´s milk in Saudi Arabia lower concentration of Zn (3.09 mg/kg), Ca (822.50 mg/kg) and higher concentration of Cu (0.62/mg) and Fe (5.01 mg/kg). In milk of Bulgarian breeds of sheep (Strednostaroplaninska and Tetevenska sheep) Gerchev and Mihaylova (2012) found similar concentrations of Ca (223 and 208 mg/100g) as well as higher concentration of Fe (0.181 and 0.12 mg/100g).

The concentrations of elements in raw milk are also affected by animal forage, feed and water (Dobrzański et al., 2005; Al-Wabel, 2008). Animal feed with elevated levels of these elements causes also an increase of their level in milk (Bushra et al., 2014). Concentrations of health-beneficial elements, e.g. Fe, Zn in milk are dependent on the animal species, feed, milk sample collection time, environmental conditions and manufacturing processes (Herwing et al., 2011). Changes in composition of milk can also be affected by many genetic (breed, herd) and physiological factors (lactation, age, animal health), but also the environment (food, climate, season, method of milking) (Komperej et al., 1999).

Tab. 3 Concentrations of essential elements in sheep´s milk during different stages of lactation

Element mg/kg	Stage of lactation (Mean±SD)		
	Early	Middle	Late
Ca	2560.00±1.58[a]	1040.00±1.58[c]	1590.00±1.58[b]
Mg	187.00±1.58[a]	1040.00±1.58[c]	179.00±1.58[b]
Zn	8.00±0.16[a]	8.00±0.16[a]	2.20±0.16[b]
Se	<0.030	<0.030	<0.030
Fe	<0.50	1.30±0.16	0.81±0.002

SD- standard deviation; [a,b,c] means within a row with different superscripts differ (p<0,05); [a] means within a row with the same superscripts- non significant

Conclusions

The results indicate that content of selected essential elements and toxic metals in feed and milk changes depending on the season of year and lactation stage. The work showed significantly increase content of Ca, Mg, Se and Fe during the lactation stage. Concentration of essential element (Cu) and toxic elements (As, Cd, Hg, Ni, Pb) in milk was low, below the LOQ. It can be concluded, that the use of milk of sheep from this area for direct use or for dairy products processing is appropriate, safe and poses no health risk for the consumers.

Abstract

Both, genetic and feeding factors, affect beef quality. Although breed or type contributes significantly to the genetic variation in beef quality, nutrition is one of the most important factors. The aim of our research was to study the influence of feeding of pea on beef meat quality. We had two groups with different feeding: ordinary feed ration and feed ration with pea. Three calves from each group were slaughtered (live weight 250 kg) at a commercial slaughterhouse via electrical stunning, followed by exsanguinations, and carcasses were dehaired via scalding, eviscerated, and split vertically down the midline. Hot carcass weights were obtained and measured. The samples of meat were taken from the *musculus longissimus lumborumetthoracis* 24 hours *post mortem* and subsequently subjected to the chemical analysis. The carcass traits in our studies were not influenced by peas included in beef cattle calves diets: carcass outcome weight was from 58 to 62%, muscle-eye area 62-76 cm^2. Higher results were in pea cattle group. The chemical content of meat also did not differ significantly, except crude protein, 24.1±0.16 and 24.9±0.31, respectively. The higher was in pea cattle group ($p<0.05$). The other indices were similar in both groups: crude fat 1.7±0.19 and 1.6±0.20, cholesterol, mg 100g - 56.0±3.99 and 58.2±4.79, ph 5.4±0.11 and 5.3±0.15. The pH of muscle considered "normal" was 5.6. Muscle color, texture, water-holding capacity and tenderness were influenced by pH. The pH in beef meat ranged from 5.3-5.4 in our research, a little less than in"normal" meat. This indicates that the animals may have been killed in stress. The concentrated feed with peas in cattle diets make beef carcasses more muscular.

Key words: *beef meat, pea, feeding, carcass traits.*

Introduction

Field pea contributes significant amounts of protein, carbohydrates, and amino acids to all species, but is increasingly considered an excellent ingredient in beef, dairy, pig and poultry rations due to their nutrient density. The crude protein content of field pea may vary due to the influence of variety and environment. Because of this variation, field pea should be tested for protein for inclusion in balanced livestock rations. Field pea compares favorably with other grains and co-products for several nutrients. Pea are considered a crude protein source in most diets. Energy levels are similar to corn for most livestock species with starch (54%) and digestible fiber (hemicellulose fraction 7%) accounting for most of this fraction. Fat is a modest contributor at 1.55% (Walhain et al. 1992). Amino acids are important to pig and poultry, but not a major concern to ruminants as microbes in the rumen provide the required amino acids for beef and dairy cattle and sheep. However, rate and extent of ruminal degradation for both starch and protein are important to ruminants. In cattle nutrition, utilization of pea seeds is limited, particularly in high-producing cows, where the need for undegradable protein is likely to be high. Therefore, pea protein is characterized by high solubility and ruminal effective degradability (Walhain et al. 1992). Protein value attributed to pea in the Feed Tables, which is largely influenced by effective degradability, is very low. The effective degradability value is obtained from the nylon bag method, which is strickly and carefully standardized. In this method, tested feeds are ground through a 0.8-mm screen. A more coarse grinding, as in practice, could reduce ruminal effective degradability and improve protein value. Several experiments have been conducted to investigate the effects of particle size on rate and extent of breakdown in the rumen of different feeds for example barley, corn, soy, wheat, lupin seeds (Kibelolaud et al. 1991). There is lack of data in the literature on the effect of grinding on rumen escape of pea crude protein and starch (Bayourthe et.al., 2000). The aim of the our research was to determine the efficiency of feeding of pea into concentrated feed mixture of the beef cattle calves rations and to study its effect on meat quality.

Materials and methods

Animals and housing. The twenty pure Charolais breed beef cattle calves were allotted to trial. The research was done in one farm in Latvia. Two groups of growing beef cattle calves with their mothers were conducted for trial in summer time. The calves received concentrated feed in special feeding equipment.The animals were 90 days old at the start of the experiment. The calves were raised from 110 kg to weaning weight. The one calves group received pea 15% (trial group) blended into a mixture of concentrated feed, but control group only mixed concentrates. We used field pea, which harvested as grain, with chemical content: crude protein 25.87%, acid detergent fiber 9.03%, neutral detergent fiber 17.97%, starch 48.16%, calcium 0.09%, phoshorus 0.57% in dry matter. The field pea (15%) we mixed together with barley (27.5%), wheat (27.5%) and oats (30%). This concentrate feed received trial beef cattle group (10 calves in growing period), but control group only mixed grains barley (27.5%), oats (45%) and wheat (27.5%). Control and trial groups animals received mixed feed with chemical content, respectively, crude protein 11.0% and 14.3%, starch 55.9% and 54.4%, acid detergent fiber 8.81% and 8.18%, neutral detergent fiber 22.59% and 18.15%, the energy content 8.8 and 7.9 NEL, MJ kg $^{-1}$ in dry matter. The basic feed was grazing grass with crude protein 10.3% for both beef cattle groups.

The chemical analyses of the pea, the prepared concentrated feed and grass were determined in the laboratory. During the study the live weight of calves was monitored, and the feed consumed was counted.

Three calves from each grop were slaughtered at a commercial slaughterhouse via electrical stunning, followed by exsanguinations, and carcases were dehaired via scalding, eviscerated, and split vertically down the midline.

Hot carcass weights were obtained and was measured muscle-eye area with the planimeter. The carcass was devided into fractions for determination muscle and fat. The samples of meat were taken from the *musculus longissimus lumborum et thoracis* 24 hours *post mortem* and subsequently subjected to the chemical analysis.

Analytical Methods. Diets and ingredients were milled through a 1-mm screen before analysis. The dry matter (DM), crude protein (CP), acid detergent fiber (ADF), neutral detergent fiber (NDF), starch, fat, Ca and P contents were analyzed based on standard methodology, respectively DM with ISO 6496: 1999, CP with LVS EN ISO 5983-2: 2009, Ca with LVS EN ISO 6969: 2002, P with ISO 6491: 1998, ADF with LVS EN ISO 13906:2008 and NDF with LVS EN ISO 16472:2006. The neto energy (NEL) were calculated according to equation (Mc Donald et.al., 2002; Morgan,1975). The quality indicators for nutrients were determined by the accredited laboratory of Agronomic analysis of the Latvia University of Life Sciences and Technologies. The chemical analysis of meat were determined by LVS ISO 1442:1997 for water, LVS ISO 1443:1973 for fat and LVS ISO 937:1978 for crude protein content, LVS ISO 2917:2004 for ph and BIOR-T-012-132-2011 for cholesterol content in laboratory of Food and Environmental Investigations (BIOR) in Latvia.

Statistical analysis. All data were statistically processed to determine the differences between diets. Statistical analysis was performed according to the General linear Model procedure of

SAS/STAT 9.22 software package (2010). Most data was reported as aritmetic means with the pooled SEM. The treatment means were compared using Student's *t-test.* Statements of statistical significance were based upon $P<0.05$.

Results and discussion

The results showed that 15% inclusion of pea in beef cattle calves diets signicantly increase daily liveweight gain (Table1.). The daily liveweight gain were 1.1±0.04 kg and 1.3±0.55 kg, respectively in control and trial calves groups.

Table 1. Beef cattle calves growth rates (n=12)

Indices	Control group	Trial group
Liveweight at the beginning of the growing period, kg	110±24.2	118±25.6
Liveweight at the end of growing period, kg	245±23.5*	281±22.0*
Liveweight gain, kg	135	163
Growing period, days	123	123
Liveweight gain per day, kg	1.1±0.04*	1.3±0.55*
Liveweight at the age of 200 days, kg	202.7±12.9*	249.6±21.9*

*p<0.05

The increase of liveweight gain per day was 0.2 kg higher for a group fed concentrate with pea. Beef cattle live weight was significantly higher also *(p <0.05)* at 200 days of age by 46.9 kg. Field pea is a very palatable feedstuff for all classes of beef cattle. This feed may best be used in diets where nutrient density and palatability are important, such as creep feeds (Bayourthe et al., 2000). Feeds with 33% to 67% field peas produced optimum animal performance and return. This formulation may provide excess crude protein as creep feed recommendations call for no more than 16%. Weaned calves can be fed pea at essentially any proportion of the concentrate when grains and supplements make up 60% or less of the total diet. Dietary crude protein requirements for growing steers and heifers are based on gain goals, with higher protein required for faster growth. Maximum recommendations are 13.5 to 14% crude protein in the diet. Peas fed at more than 25% of the total diet will probably result in excess crude protein, but like the creep feed trials, slightly improved performance was observed over the control diet when peas were included at 50% or more of the concentrate. The economics of using field peas at levels higher than 25% of the total diet should be carefully considered (Bayourthe et al., 2000). Finishing cattle have demonstrated some improved performance traits with up to 20% field peas in the diet. Field pea works well in beef cow supplements at most any level. The nutrient density will provide additional benefits as fewer finances of feed will be required for the same nutrition, resulting in lower transportation and storage costs. Field pea may be fed in place of range cake as a protein and energy source for wintering cows or incorporated into range cake at any level required. Field pea makes an excellent binder for pelletting or cubing. No anti-nutritional traits were observed in field pea fed to feedlot and breeding beef cattle at up to 76% of total dry matter intake. Both starch and protein from field peas degrade slowly but relatively thoroughly in the rumen, with only modest levels of escape protein (Bayourthe et al., 2000).

Nevertheless, to peas inclusion in feed mixture, the consumed concentrated feed for one calves during the our research period in control and trial group were, respectively 49.5 and 51 kg and feed consumption per 1 kg liveweight gain did not differ significantly between the research groups. The concentrated feed costs per 1 kg live weight gain was similarly (0.05 EUR).

We know that both genetic and environmental factors affect beef quality. Although breed or type contributes significantly to the genetic variation in beef quality, but nutrition is one of the most important environmental factors (Melton, 1990). Nutrition significantly affects the rate of conditioning and consequently carcass composition, conformation, meat yield and meat and fat quality. In addition to tenderness, the importance of fat quality has increased because it contributes towards the appearance, palatability, nutritive value, processibility, shelf life and ultimately the acceptability of beef. Emphasis is increasingly placed on the production of edible lean with a minimum of excess fat, but reducing fat to too low levels may adversely affect eating satisfaction. Beef quality can be manipulated by a variety of nutritional interventions, many of which have been implemented successfully in feedlots world-wide. The carcass traits in our studies did not influenced by peas inclusin in beef cattle calves diets (Table 2.).

Table 2. Carcass traits (n=6)

Carcass indices	Control group	Trial group
Carcass evaluation (SEUROP)	U	U
Carcass outcome weight,%	58	62
Muscle-eye area, cm^2	62	76
Muscle in carcass, %	69.9	71.1
Fat in carcass, %	2.5	3.0

The chemical content of meat also did not differ significantly, except crude protein, 24.1±0.16 and 24.9±0.31, respectively. The higher was in pea cattle group ($p<0.05$). The other indices were similar in both groups (Table 3). In the other scientist research, fifteen experiments which compared forage and grain finished beef at the same carcass weight or degree of fatness, have been selected from the literature (Muir et al., 1998). When compared at similar carcass weights or the same degree of fatness, the type of feeding system had no effect on tenderness, juiciness, lean meat colour, marbling, or pH. In eight out of twelve experiments where flavour was assessed, panellists could not distinguish an effect of diet on flavour. Effects on fat colour were variable and, in six of the nine experiments where fat colour was measured, grain feeding failed to "improve" fat colour. It is concluded that there is little scientific justification for the claim that grain feeding is necessary to produce high quality beef. Beef of comparable quality can be obtained from cattle finished on forage based diets (i.e., pasture) provided that acceptable carcass weights and degrees of finish can be achieved at a young age (Muir et al., 1998).

Table 3.The chemical content of meat in dry matter (n=6)

Chemical content	Control group	Trial group
Dry matter,%	29.8±0.11	29.6±0.61
Crude protein, %	24.1±0.16*	24.9±0.31*
Crude fat,%	1.7±0.19	1.6±0.20
Ph	5.4±0.11	5.3±0.15
Cholesterol, mg 100g	56.0±3.99	58.2±4.79

*$p<0.05$

The pH of muscle considered "normal" is 5.6 (pH is the negative log of the hydrogen ion concentration; the higher the pH, the less acidic is the muscle). Muscle color, texture, water-holding capacity and tenderness are influenced by pH. The Ph (Table3.) in beef meat were from 5.3-5.4, a little less then in meat" normal".This indicates that the animals may be were killed in stress.

Conclusions

The daily liveweight gain of beef cattle were 0.2 kg higher for the group fed peas. The live weight of the young cattle at the age of 200 days differed significantly *($p<0.05$)*. The pea groups cattle were 46.9 kg heavier. The concentrates feed with peas in cattle diets make beef carcasses more muscular.

Acknowledgments

A study on the effective usage of the concentrated feed supplement to Beef calves was carried out within the framework of the project "Zootechnical and economic efficiency of feeding of fodder pulses to ruminant's meat production".

Abstract

Main goal in cattle reproduction is to achieve high fertility with economical justification for duration of open days or intercalving period. This period in optimal conditions should last 12-13 months, which in return gives best milk production in lactation year. Utilisation of biotechnological measures in control of reproductive functions, it is possible to increase reproductive performances in dairy cows. Induction and synchronisation of estrus usualy require utilisation of hormones for control of ovarian activity and to reduce unsuccessful artificial inseminations. Final goal is to reduce open days/service period to prevent or reduce financial losses. Our study has included 187 cows. Anamnestic data have been taken from reproductive/health card. Before hormonal treatment, all cows had clinical examination of reproductive system. First group had primiparous and multiparous cows which have received prostaglandin F2α in period 40-80 days postpartum, while second group had primiparous and multiparous cows which have received GnRH in period 10-14 days postpartum. Status of ovaries, uterus and pregnancy, have been done with manual and sonographic transrectal examination, while progesterone levels have been assessed using RIA method. Prostaglandin F2α application to multiparous cows, had reduced open days period for 20 days, but same application to primiparous cows had increased open days duration for 30 days. Treatment of multiparous cows with GnRH had signifficant shortening of open days period for 90 days, but same treatment in primiparous cows had reduced percent of conception. Our study has shown that optimum of reproductive performances could be achieved with application of GnRH hormone soon after parturition and timely application of prostaglandin F2α after 40 days postpartum, when histological regeneration of uterine endometrium is complete.

Keywords: *primiparous, multiparous, cow, hormone, reproduction, service period*

Introduction

Main mission of reproduction in cattle husbandry is to achieve high fertility and pregnancy rate. Intercalving period is one of the most representative sign of reproduction success and it should be ideally 12-13 months long, when cows have best reproductive and productive performances. Using breed selection to maximize their genetic potential, signifficant increase in milk production have been achieved in recent decades (Butler, 1981)

Management of reproduction is one of the most important steps toward economical success of any dairy farm. Numerous studies have shown that reproductive ability in dairy cows is compromised, mainly because of late postpartum ovarian cyclicity. Prolonged postpartum anestrus have negative influence to productive ability and profitability of dairy herd (Diskin,

2008). Main negative effect of prolonged postpartum anestrus is seen in longer intercalving period. Increasing intercalving period in dairy cows means, increase of open days period (service period), which in return decrease profitability of those animals. When cows are out of optimum time period to achieve pregnancy, milk production starts to decrease which make them less profitable and increase rick of culling.
Many studies have proven decrease of reproductive efficiency in high yield dairy herds, seen as longer anestrus period, increase of cows with silent and short estrus, low conception rates, uterine abnormalities, which altogether results in more frequent unsuccessful arteficial inseminations (AI) (Iglesia, 1996). Utilisation of appropriate biotechnology methods in control of reproductive functions, it is possible to have influence in reproductive performances. Most often methods of induction and synchronisation of estrus are used to shorten anestrus periods and increase AI success (Chebel, 2004).
Control of ovarian cyclicity in cows and heifers is achieved with utilisation of hormones like GnRH, prostaglandins, estrogens, progesterons or mainly hormones which stimulates release of pituitary hormones.
Goal of this study was to investigate utilisation of hormones to induce ovulation and synchronise estrus in primiparous and multiparous cows in farm conditions and to reduce time period from partus to fertile estrus.

Material and methods

Our study has included 187 cows from free stall dairy farm „Spreča", which have 800 dairy cows, located in Gornje Vukovije – Tuzla Canton. All anamnestic notes were taken from reproductive/health card and all experimental and control cows had manual/ultrasonography transrectal examination of reproductive system.
First group was consisted of primiparous and multiparous cows to receive injection of PGF2α (Estrumate 10 ml, MSD Animal Health) and one control group:

- Multiparous cows (n=38) to receive PGF2α in period 40-80 days pospartum
- Primiparous cows (n=40) to receive PGF2α in period 40-80 days pospartum
- Control group of multiparous cows (n=8) and primiparous cows (n=12)
  Second group were consisted of primiparous and multiparous cows to receive GnRH (Receptal - MSD Animal Healt) at 10. – 14. days postpartum and one control group:
- Multiparous cows (n=34) to receive GnRH at 10.-14. days postpartum
- Primiparous cows (n=38) to receive GnRH at 10-14. days postpartum
- Control group of multiparous cows (n=10) and primiparous cows (n=7)

AI have been performed one time in period 11 to 13h, but if cows had signs of observed estrus next day, they were inseminated again. Pregnancy examination have been done 34 to 38 days after insemination. Norms for comaparation of results have been length of open days period and conception rate. Statistical data processing was done using software Microsoft Excel 2010, method of descriptive statistics and t-test to determine significant differences. All differences from $p<0,05$ are considered as significant.

Results and Discussion

Table 1. Length of postpartum period and conception rate after first AI in treated primiparous and multiparous cows

	Period postpartum multiparous cows	**Period postpartum primiparous cows**	**Conception rate multiparous cows**	**Conception rate primiparous cows**
Average	51,94	55,15	0,39	0,52
Standard Deviation	1,49	2,01	0,08	0,07
Min	39	27	-	-
Max	73	78	-	-
%	/	/	39,48%	52,5%
Total	326	190	326	190

Postpartum period in multiparous cows is a little bit shorter (3.21 day) compared to primiparous cows. Conception rate in primiparous cows is 52.5% and represents significant difference compared to multiparous cows, which have conception rate of 39.48%.

Table 2. Primiparous and multiparous cows with PGF2α applied at 40. – 80. days postpartum, which had conception after first, second or third artificial inseminations (AI).

	First AI	Second AI	Third AI
Multiparous cows (n=38)	*9/38* *23,68%*	*16/38* *42,1%*	*7/38* *18,42%*
Primiparous cows (n=40)	*20/40* *50%*	*11/40* *27,5%*	*5/40* *12,5%*
Control multiparous cows (n=8)	*3/8* *37,5%*	*3/8* *37,5%*	*--/8*
Control primiparous cows (n=12)	*4/12* *33,3%*	*3/12* *25%*	*1/12* *8,33%*

In table 2. it is seen that most multiparous cows treated with PGF2α in period 40. – 80. days postpartum had successful conception in second AI (42,1%), while from the first much less (23,68%) and least from the third AI (18,42%). Primiparous cows had best conception in first AI (50%), then second (27,5%) and then in third AI (12,5%). Control primiparous and multiparous cows have had lower results, compared to experimental group, what could be sign of lower estrus detection.

Table 3. Primiparous and multiparous cows with GnRH applied 10. – 14. days postpartum which had conception after first, second or third artificial inseminations (AI).

	First AI	Second AI	Third AI
Multiparous cows (n=34)	*6/34 17,64%*	*18/34 52,94%*	*5/34 14,70%*
Primiparous cows (n=38)	*11/38 28,94%*	*17/38 44,73%*	*3/38 7,89%*
Control multiparous cows (n=10)	*1/10 10%*	*5/10 50%*	*2/10 20%*
Control primiparous cows (n=7)	*1/7 14,28%*	*3/7 42,85%*	*3/7 42,85%*

In table 3. it is seen that most multiparous cows treated with GnRH 10. – 14. days postpartum had successful conception in second AI (52,94%), while from the first (17,64%) and third (14,70%) much less. Primiparous cows had most conception after second AI (44,73%) and less after first (28,94%) and second AI (7,89%).

According to McDougall (2006) reproductive performances in dairy cows have continuous decrease in farm conditions, as well as in pasture. To accomplish intercalving period of 12-13 months, high level of reproductive performances have to be achieved. Same author quote that out of 80% cows observed in estrus and first time inseminated after 60-80 open days period, conception achieve 55 do 65% cows.

From available literature it is clear that for optimal open days/intercalving period, reproductive efficiency have to be provided (Mutevelić, 2002). Timely estrus detection and AI after parturition is one of the most important measure to enhance reproductive performances, because every non-observed estrus prolong open days period for another 18-25 days. Many factors which depend of each other must be fullfilled to achieve these goals, because none of them working alone is not enough (Crowe, 2008).

Islam et al. (2013) had treated 40 cows with PGF2α at 60 days postpartum and AI had been done in observed estrus. In their study 75% cows had positive response after 2-3 days, which coincides with our results where we had most positive responses at second and third day after application (67,94%). In same study conception was signifficantly higher in treated cows (57,5%) compared to control group ($P<0,05$), which did not happen in our study, where we had better conception in multiparous cows after second AI (42,1%) and better conception in primiparous cows after first AI (50%). Out of 38 treated multiparous cows in our study, 5 cows or 13,15% did not had response to PGF2α application and reason is dystocia ie. uterine dislocation after parturition. One cow without positive response had caesarean section, while other 5 cows have had inflammation of uterus and prolonged postpartal interval.

Important role of GnRH utilisation is prophylactic and therapeutical, which should help in reactivation of ovarian cyclicity in dairy cows in postpartum period, which should have positive effect to earlier AI and better conception (Mlaćo. 2000).

According to Bosu et al. (1987) first postpartum ovulation is after 15-30 days, while 10-15% cows have abnormal ovarian activity during first 2 months postpartum and pituitary response to GnRH application increase with longer time period after parturition. Their conclusion was that GnRH application 2 weeks after parturition, should reactivate ovarian cyclicity. In our study, primiparous and multiparous cows after GnRH application 10 – 14 days postpartum, had clinicaly observed estrus in period 40-80 days postpartum and conception of 19,44%, which coincide with results from Bosu et al.

Conclusions

- Prostanglandin F2α application to multiparous cows have satisfactory results with shortening open days period, but same procedure in primiparous cows leads to longer service period.
- Multiparous cows treated with GnRH have better conception after second AI and shorter service period, while in primiparous cows same procedure have less success.
- During puerperium period, regardles on parturition difficulty, all cows should have routine control of reproductive system as well as frequent utilisation of different hormones to achieve shorter intercalving period.

EFFECT OF DIFFERENT NITROGEN FERTILIZER APPLICATION LEVELS ON YIELD AND QUALITY OF THE GREEN FODDER *TRICHANTHERA GIGANTEA*

Tu Quang HIEN*, Tu Trung KIEN, Mai Anh KHOA, Tran Thi HOAN, Tu Quang TRUNG

Thai Nguyen University of Agriculture and Forestry, Thai Nguyen Province, Viet Nam
* Corresponding author: tqhien.dhtn@moet.edu.vn

Abstract
The purpose of this study was to determine the effect of different nitrogen (N) fertilizer application levels on leaf yield and quality of the green fodder *Trichanthera gigantea* as material for leaf meal production for poultry feed in order to improve meat and egg quality. The experiment included five formulas (NT) representing five different nitrogen applications, namely NT1: 0kgN, NT2: 20kgN, NT3: 40kgN, NT4: 60kgN and NT5: 80 kgN/ha/cutting. All five formulas were arranged in a complete block randomized design with five replicates for each formula. The other factors such as plantation density, cutting height and cutting intervals were similar among the treatments. The results showed that from NT1 (0kgN) to NT5 (80kgN/ha/cutting), the leaf dry matter yield was 10.33, 11.22, 11.85, 12.13 and 12.15 tons/ha/year, respectively; the crude protein yield was 2.41, 2.70, 2.95, 3.15 and 3.24 tons/ha/year, respectively. Thus, the increase of nitrogen application from 0kgN to 80kgN/ha/cutting had decreased 10.8% dry matter in the fresh leaf, increased 14.1% crude protein on leaf dry matter and decreased 11.6% crude fiber on leaf dry matter. Based on the statistical analysis of leaf dry matter, crude protein yields and the chemical composition of leaves, it is recommended that the application of nitrogen fertilizer for *Trichanthera gigantea* should be at 40 – 60kg N/ha/cutting.

Keywords: *Nitrogen fertilizer levels, Foliage yield, quality, Trichanthera gigantea*

Introduction
In order to introduce a green fodder variety as the ingredient into animal feed, it normally takes two steps: *i)* studying on plantation and nutritive value; *ii)* studying on its utilization. For the first phase, it is usually to study a number of factors which have major effect on plant yield and quality such as plant varieties, plantation and harvesting technique, fertilizer application etc. in which, nitrogen fertilizer was the priority to evaluate. The study on optimal level of N fertilizer application for the green fodder *T.gigantea* is the first phase on plantation research. It was believed that Nitrogen fertilizer is the major factor which makes a great contribution to the yield and quality of the green fodder. Kien et al. (2011), Hoan et al. (2011), Tuan et al. (2011), Quang et al. (2012), Hong et al. (2014), Kien and Hoan (2014) Nhung et al. (2018) have reported that the optimal increase of N fertilizer not only significantly improved green fodder yield but also improved its quality, eg. Improved crude protein content, decreased crude fibre content in dry matter basic . A low level of application may give lower efficiency, but a high level of application may give negative effects on the development of the plants such as weakness, falling or death (Hien et al., 2002). Therefore, it is necessary to investigate the most suitable level of Nitrogen fertilizer application for *T. gigantea.*

Materials and methods
This study focused on green fodder *Trichanthera gigantea* and it was conducted at Thai Nguyen University of Agriculture and Forestry, Thai Nguyen Province, Vietnam from March 2017 to March 2019.The experiment included 5 treasments representing 5 different Nitrogen fertilizer levels, which abbreviated as NT1: 0kgN, NT2: 20kgN; NT3: 40kgN; NT4: 60kgN and NT5: 80kgN/ha/cutting. The short name of treatments was as 0N; 20N; 40N; 60N and

80N. The plantation area of each treasments was 24 m^2 with 5 replicates, and arrangeed in a completely random block design. All 5 treatments had the similar plantation density, cutting intervals, cutting height and fertilizer application level (except N - fertilizer).

The monitoring parameters include productivity and yield of biomass, fresh leaves, dry matter, crude protein and chemical composition of the *T. gigantea* leaves. These parameters were determined by the method from Hien et al. (2002). The chemical composition of the green fodder was analysed following A.O.A.C. (1990). Each criterion was analyzed with 5 replicates (n=5).Collected data was processed following the method from Oanh and Phu (2012) with IRRISTART 5.0.2009 software.

Results and discussion

Effect of nitrogen application levels on productivity of *T.gigantea*

The green fodder productivity was determined by following parameters: *i)* biomass productivity, *ii)* fresh leaf productivity and *iii)* dry matter productivity. These parameters were expressed as weight of biomass or fresh leaves or dry matter received per each harvest per ha, the unit expressed as quintal/ha/cutting (or harvesting). The average productivity of biomass, fresh leaves, dry mater/ha/cutting of 2 experimental years are presented in Table 1.

Table 1. The productivity of *T.gigantea* at different N- levels (quintal/ ha/ harvest)

N - levels	Biomass	Fresh leaves	Dry matter
0 N	182.04^{c}	113.88^{c}	18.78^{b}
20 N	203.35^{b}	127.21^{b}	20.41^{ba}
40 N	220.46^{ab}	137.92^{ab}	21.54^{a}
60 N	232.23^{a}	145.29^{a}	22.05^{a}
80 N	240.11^{a}	150.21^{a}	22.10^{a}
SEM	11.122	6.958	1.087
P	0.000	0.000	0.000

Note: 1quintal = 100 kg

Effect of nitrogen application levels on biomass productivity

The biomass productivity includes the entire stems, branches and leaves of green forage crops obtained on 1 ha in a harvest. It is an important parameter to calculate fresh leaves and dry matter productivities. When nitrogen application level increased from 0N to 80N/ha/cutting, the average biomass productivity per cutting of the two years increased from 182.04 to 240.11 quintal/ ha/ cutting.The relationship between N application level and biomass productivity was expressed by the following equation: $Y = 0.725\ x + b$; R= 95.5%. In which, *Y is biomass productivity (quintals/ha/cutting); X is nitrogen application level (kg N/ha/cutting).* This equation showed that the level of N application and biomass productivity has a significant correlation (R=0.95).

The results of statistical analysis and comparision showed that the average biomass productivity per cutting of the two years for the N application level of 20N was not significantly different from that of the 40N level; the data also showed no significant difference among 60N, 80N levels and 40N level. It can be explained as follows: the application level of 60N and 80N satuated the nitrogen requirement, thus the biomass productivity was not remarkedly increased. The following collected data proved this phenomenon: The average biomass productivity of the 2 years in 20N level was higher than that of 0N by 11.7%; that of 40N was higher than that of 20N by 8.4%; that of 60N was higher than that of 40N by 5.3%; that of 80N was higher than that of 60N by 3.4%. It can be seen that the increase of N application levels was not strongly correlated with the increase of the biomass productivity.

Other studies such as those on different N application levels for *P. atratum* grass from Kien et al. (2011), for cassava leaves production from Hoan et al. (2011), for some grass varieties from Quang et al (2012), for green fodder *M. oleifera* from Nhung et al. (2018) also showed the similar results. Accordingly, the increase of N application level resulted in increasing biomass productivity; however, when the N application was too high, this productivity even decreased.

Effect of nitrogen application levels on fresh leaf productivity

Leaf meal supplemented into chicken and rabbit complex diets was produced from green fodder leaves when stem and branches were removed and leaves were dried then ground to fine powder. Thus, it is very important for the producers to have knowledge on fresh leaf productivity of the green fodder. Fresh leaf productivity can be calculated by multiplying biomass productivity with the proportion of fresh leaves per biomass. The proportion in this experiment was determined as 62.56%. The average fresh leaves production of 2 years increased from 113.88 quintal (NT1) to 150.21 quintal/ha/cutting (NT5). Statistical analysis showed that the average productivity of fresh leaves of 2 years production of those received N fertilizer was significantly higher than those which did not receive any N fertilizer (0N) ($p < 0.001$); among those receiving N fertilizer, NT2 (20N) and NT3 (40N) were not significantly different; NT3 (40N), NT4 (60N) and NT5 (80N) also differed insignificantly ($p > 0.05$) due to the above mentioned reason.

Effect of nitrogen application levels on dry matter productivity

Dry matter productivity was calculated by multiplying fresh leaves productivity with dry matter content in fresh leaves. The dry matter content in fesh leaves was different in negative correlation with different N application levels; the lower application level of N, the higher dry matter content and vice versa; particularly, from NT1 to NT5 this contents were 16.49%; 16.04%; 15.62%; 15.18% and 14.71 % respectively. The average dry matter productivity of 2 years increased from 18.78 quintal (0N) to 22.10 quintal/ ha/ cutting (80N). The difference in productivity of dry matter in NT5 (80N) compared to NT1 (0N) was notably lower than that of fresh leaves productivity in these 2 treatments. It can be illustrated as: the difference in dry matter productivity between NT5 and NT1 was 11.68%, whereas that of fresh leaves was 31.90%. It might due to that when the application of N level increased, the dry matter content in fresh leaves decreased. For example, DM content of fresh leaves in 0N and 80N was 16.49% and 14.71%, respectively.

Trichanthera gigantea production yield at different N application levels

Production yield is the total biomass or fresh leaves productions, dry mater, crude protein harvested per ha per year. Production yield can be estimated by two means, namely *i)* accumulating productivity of all cuttings/ha/year, or *ii)* taking the average productivity of the cuttings to multiply by the number of cuttings per year, then converting from quintals/ha/year to tons/ha/year. Crude protein yield was calculated by multiplying DM yield with CP content in DM. Average yield of above parameters of the 2 years were presented in Table 2.

Table 2: *T.gigantea* yields at different N application levels (ton/ha/year)

N - levels	Biomass	Fresh leaves	Dry matter	Crude protein
0 N	100.122^{c}	62.636^{c}	10.329^{c}	2.412^{d}
20 N	111.841^{b}	69.968^{b}	11.223^{bc}	2.700^{c}
40 N	121.253^{ab}	75.856^{ab}	11.849^{ab}	2.950^{bc}
60 N	127.729^{a}	79.907^{a}	12.130^{a}	3.125^{ab}
80 N	132.062^{a}	82.618^{a}	12.154^{a}	3.239^{a}

SEM	6.117	3.827	0.598	0.149
P	0.000	0.000	0.000	0.000

Table 2 showed that the increase of N levels from 0N to 80N per ha per cutting resulted in the increase of biomass yield and fresh leaf yield by 31.9%, DM yield increased by 17.7% and CP yield increased by 34.3%. The difference in DM was smaller than that of the biomass and fresh leaves because when N level increased, DM content in the leaves decrease. Whereas, the difference seen in CP was larger than that of biomass and fresh leaves because when N level increased, CP content in fresh leaves (or DM) increased. In this study, CP content in DM from NT1 to NT5 was 23.35%; 24.06%; 24.90%; 25.75% and 26.65%, respectivlely.
The results of statistical analysis revealed that biomass and fresh leaves, DM yields of treatment 60N, 80N were significantly higher than that of 0N, 20N with $p<0.001$, however, this difference was not seen when compares to that of 40N treatment ($p>0.05$); that of 40N was significantly different from that of 0N ($p<0.001$). CP yield was insignificantly different between 80N and 60N, between 60N and 40N; between 40N and 20N; however, all the treatments with application of N resulted in the increase of CP yield compares to those did not receive any N (0N) with $p<0.001$. Thus, increased N application level significantly increased CP yield. The DM yield of the 40N treatment was not significantly different from that of 60N and 80N treatments; however, CP yield of this level was only remarkably lower than that of 80N; whereas, the CP yield of 60N and 80N was not significantly different. Thus, the N application levels of 40N and 60N were selected as the most suitable levels.
Research results on some other green food plants indicated that the average yields of dry matter and crude protein (ton/ha/year) of casava for leaf production were 9.23 and 2.21 (Hien and Trung, 2016), of S. guianensis grass were 7.25 and 1.35 (Hien et al, 2017), of L. leucocephala were 8.49 and 2.36 (Hoan et al, 2017), of M. oleifera were 9.40 and 3.16 (Nhung et al, 2018). Thus, dry matter and crude protein yield of *T. gigantea* in this experiment was greater than or similar to that of some other food crops which are often used to process leaf meal in Vietnam as reported by previous authors.

The DM and CP production efficiencies of the different treatments

The DM and CP production efficiencies of the different N application levels were estimated by taking DM and CP yields from NT2, NT3, NT4 and NT5 substract to DM and CP yields of NT1, converting the results from ton/ha/year to kg/ha/year then dividing by the total N used for 1 ha per year. The results were shown in Table 3.

Table 3. The efficiency of different N application levels at 2 years production

Parameters	Unit	NT2 20N	NT3 40N	NT4 60N	NT5 80N	SEM	P
DM added	Kg	894^{c}	1520^{b}	1801^{a}	1824^{a}	42.256	0.009
CP added	Kg	288^{d}	539^{c}	713^{b}	827^{a}	1.919	0.000
N/ha/year	Kg	110	220	330	440		
DM/N Efficiency	KgDM/kg N	8.13^{a}	6.91^{b}	5.46^{c}	4.15^{d}	0.154	0.000
CP/N Efficiency	Kg CP/kg N	2.62^{a}	2.45^{b}	2.16^{c}	1.88^{d}	0.006	0.000

Data in Table 3 showed that at the higher levels of N application, the addition of DM and CP per ha per year were increased significantly ($p<0.001$). In contradiction to that, the dry matter and crude protein per 1kgN was decreased significantly ($p<0.001$). It should be noted when applying N fertilizer for *T.gigantea*, if more DM, CP yields per ha per year is desired regardless of production cost then higher level of N application should be used (60 – 80 kgN/ha/cutting); if cost of production is taken into consideration then N application of 40 N – 60 kgN/ha/cutting should be the suitable levels.

Effect of different N application levels on the quality of *T.gigante*

Effect of different N application levels on *T.gigantea* quality was determined via chemical analysis of the leaves, such as: dry matter (DM), crude protein (CP), crude fat (ether extract - EE), crude fiber (CF), total mineral (Ash), nitrogen free extract (NFE). Obtained results were presented in following table.

Table 4. Chemical compostion of *T.gigantea* leaves

N levels	DM in fresh leaves, %	% DM				
		CP	EE	CF	Ash	NFE
0 N	16.49^{a}	23.35^{a}	2.18^{a}	11.16^{a}	21.59^{a}	41.72^{a}
20 N	16.04^{ab}	24.06^{ab}	2.37^{ab}	10.72^{a}	22.26^{ab}	40.59^{ab}
40 N	15.62^{abc}	24.90^{bc}	2.43^{b}	10.50^{ab}	22.98^{bc}	39.19^{ab}
60 N	15.18^{bc}	25.76^{cd}	2.57^{bc}	10.01^{b}	23.72^{cd}	37.94^{bc}
80 N	14.71^{c}	26.65^{d}	2.72^{c}	9.86^{b}	24.61^{d}	36.16^{c}
SEM	0.677	0.519	0.130	0.369	0.581	1.595
P	0.004	0.000	0.000	0.000	0.000	0.000

Data in Table 4 showed that when the application level of N fertilizer increased from 0 to 80 kgN, DM content in the leaves decreased by 1.78% (from 16.49% to 14.71%); in dry matter content, the CP was increased by 3.3% (from 23,35% to 26.65%), fiber content was decreased by 1.3% (from 11.16% to 9.86%), the total ash was increased by 3.02% (from 21.59% to 24.61%) and the nitrogen free extract (NFE) was decreased by 5.56% (from 41.72% to 36.16%). Thus, increase in N application level did not only improve biomass productivity but also improve biomass quality, such as increasing CP content and decreasing CF content in the feed.

The increase or decrease of these nutrients were only significantly different ($p<0.001$) when there was a difference of 40kgN/ha/cutting or more. For example: the N application level of 40N compared to 0N, 60N compared to 20N and 80N compared to 40N.

Several authors who studied on N fertilizer application for different green fodders also stated that N fertilizer had significant effect on the chemical composition, especially, on CP and CF contents in the green fodders. Kien et al. (2011) reported that the increase of N fertilizer from 0 kgN to 60 kgN/ha/cutting for B decumbens increased CP content in DM from 8.77% to 13.18%, decreased CF in DM from 39.18% to 35.16%. Hong et al. (2012), Tuan et al. (2011), Hoan et al. (2011), Kien and Hoan (2014), Nhung et al. (2018) studying on different N application levels on *Setaria* grass, cassava for leaf production, *B. brizantha*, *M. oleifera* also had similar results.

Conclusion

Increasing N fertilizer application from 0kgN to 80 kgN/ha/cutting increased dry matter yield from 10.329 tons to 12.154 tons and crude protein yield from 2.412 tons to 3.239 tons/ha/year, increased crude protein content by 3.3% and decreased crude fiber by 1.3% in leaves dry matter. Based on the results of dry matter, crude protein yields and chemical composition of the leaves, it is recommended that nitrogen fertilizer application level for *Trichanthera gigantea* should be at least 40 kgN/ha/cutting or more, the most suitable level is 60 kgN/ha/cutting.

Abstract

The paper establishes how average egg production changes in the course of one year (per month) and how egg production is independently influenced by maximum daily temperature and maximum relative ambient air humidity, as well as what their joint impact is. For the purpose of investigating into the impact of average annual temperature, air humidity and daily temperature on production properties, egg laying capacity and weight of laid eggs, the authors conducted a relevant experimental research study on the farm Šurik Invest. The research subject comprised of 25200 heads of the HISEX BROWN light line hen hybrid that were 30 weeks old at the beginning of the experiment, i.e. 47 weeks old at the end of the research period. The research lasted for 18 weeks in the period between May, 1st 2016 and August 31st 2016. By means of statistical data analysis performed by calculating the ambient air humidity index and by means of various analytical models and nomograms it was ascertained that the THI in different months and seasons of the year was in correlation with the number of laid eggs and their weight and that its intensity had impact on the productivity of laying hens. Namely, in May, when the THI was >74 and productivity was 79.13%, egg weight was 68.06 g, i.e. in August, when the THI was >84; and productivity was 68.63%, average egg weight was 67.51 g. Likewise, the number of cracked eggs increased due to low food consumption and low protein intake, i.e. from 1. 65% in May to 4.40% in August.

Key words: *laying hens, eggs, productivity, egg weight, temperature humidity index.*

Introduction

Production of eggs for human consumption is a demanding technological process which has acquired the properties of industrial production in the scope of intensive poultry farming.However, one cannot but observe that no attention whatsoever has been paid to the fundamental biological needs of poultry but merely to the matters of production efficiency and profitability. Hence, conditions created by keeping laying hens in conventional (traditional) cages, as well as ambient conditions, nutrition and external factors (air humidity, temperature, etc.) comprise the main factors which impact a flock´s productivity, as well as production results of laying hens (the number of laid eggs, egg weight, eggshell stiffness, etc.).

The greatest impact on a flock´s production results is exerted by the manner of exploitation with all the accompanying equipment which indirectly influences laying hens´ health and productivity. Whether the breeding conditions for laying hens comply with legal regulations is indeed disputable. However, one can rest assure that new regulations promise to introduce great changes in the production of table eggs in Serbia, since it is neither effortless nor cost-effective to change breeding methods and the manner of production.

There are two phases in the system of table eggs production. The first phase implies breeding of pullets for approximately 18 weeks, while the second phase comprises exploitation of hens from the beginning of the reproductive period to their exclusion, which most frequently takes place between 72 and 76 weeks of age. Hybrids which are nowadays used for producing table eggs have a very high genetic capacity. However, the extent to which this capacity is to be

exploited depends first and foremost on breeding conditions for laying hens, i.e. on the breeder.
In the production phase the optimum temperature is between 18°C and 22°C. In our region problems occur during summer months when outdoor temperature is extremely high. The consequences of high temperatures of over 33°C are reflected in a decreased food consumption and slower egg production. During intensive heat the eggshell tends to be soft, while the percentage of eggshell cracking suddenly increases followed by an intensive decrease in egg weight.
The optimum air humidity in a facility is obtained by means of proper ventilation. Low humidity has a negative impact, causing nervousness and dehydration in laying hens, as well as decrease in production. High humidity also causes nervousness in laying hens, wherebytheir feathers become conglutinated and egg production decreases. In both events hen resistance decreases and they become susceptible to infections. Optimum air humidity should be around 65% to 75%, while the required amount of air is 4 to 6 m^3 of air per hour per kilogram of live body weight.

Literature review

One of the most commonly observed occurrences in intensive poultry farming is the weakening of form and physique (Karabasil *et al*., 2013). The processes which lead to the weakening of general and specific body resistance, as well as of adaptation and acclimatisation power are unfortunately dictated by breeders and producers who removed animals from their natural ambient by being dedicated for centuries to a rather unilateral goal. They raised animals in a modified environment void of natural selection vectors such as nutrition depending on seasonal and climate cycles, the effects of pathogenic micro- and macro-organisms, livestock transportation and other factors which have been confirmed (Vecerek *et al*., 2006; Warriss *et al*., 1990).
In the process of studying laying hens, stress factors are devoted special attention. Among them one needs to emphasise environmental conditions and food quality, i.e. nutrition. Theintensity of impact of these factors on animals and the manner in which they will react in stressful situations depends first and foremost on endogenous condition of animals. Therefore it is important to establish the intensity of stress impact on hens for each farm (Ritz *et al*., 2005).
In the case of intensive breeding of laying hens, i.e. in the case of the system of keeping hens in a closed space throughout the year, one of the main issues, aside from spatial properties, are ambient conditions. Regardless of whether one encountersthe floor housing system or cage breeding, the movement of hens is largely limited which frequently causes stressful reactions in hens (Rakonjac *et al*., 2014)?
Under unfavourable ambient conditions, primarily with respect to the ventilation system, one encounters unfavourable microclimate conditions which also negatively influence animals´ mood, appetite, productivity and general health. Hens are animals with a slightly increased body temperature in comparison to other animals (optimal body temperature is 41°C), which is also related to a higher optimal ambient temperature. Numerous results indicate that the optimal air temperature for laying hens ranges between 18°C and 21°C.
In all animals as well as in hens the heat stress impacts the functions of adrenal glands and secretion of corticosteroids. The problem which one encounters when studying the functions of adrenal glands in hens is the fact that, unlike mammals, this gland is diffused in hens, which makes the complete separation impossible (Milošević *et al*., 2012).
The heat stress is doubtless one of the main stress factors which causes great losses in poultry farming.

The first symptoms of heat stress in laying hens can be observed at a temperature of 22°C, while serious problems with appetite and behaviour occur at a temperature of over 27°C. When air temperature exceeds 30°C hens stop taking food which inevitably leads not merely to productivity disruption, but also to an increased number of dirty eggs due to a more fragile eggshell, to decreased egg weight and eventually to an increase in hen demise (Perić *et al.*, 1998).
Low and especially high temperatures are a significant stress factor which influences not merely egg production but also hens´ general health.
Temperature humidity index (hereinafter: THI) has been introduced as a generally acceptable parameter. This index establishes a connection between maximum daily temperature and momentary relative humidity from the standpoint of the risk of heat stress. With an increase in temperature and ambient humidity the THI inclines towards 100. In order to establish the risk of stress various analytic models and nomograms have been defined.

The most frequently used model in research studies is as follows:

$$THI = (0{,}8\,Tmax) + \left(\frac{\varphi}{100}\right)(Tmax - 14{,}4) + 46{,}4$$

φ – Relative air humidity

THI values lower than 74 indicate that there are optimum conditions for egg production. Under these conditions there are virtually no recorded cases of stress.
When THI values are between 75 and 78 there are cases of productivity decrease. When THI values are between 79 and 84 there are intense stress reactions which significantly influence hen metabolism. Under these conditions homeostasis is infringed, which causes a decrease in productivity. When THI values are higher than 84, one is a witness to serious health disorders while productivity is almost entirely reduced
The intensity of reduced productivity as a consequence of stress caused by high THI values depends on animal age. The most sensitive are pullets at the beginning of their reproduction period (Bogosavljević-Bošković *et al.*, 2012). Aside from real THI values it is also important to establish when high values occur and how long these conditions last.
Likewise, it has been established that sudden changes in THI values as well as the length of stress do have impact on productivity. Thus, for instance, a sudden increase in these values can cause a decrease in productivity by 15%.

Material and Methods

For the purpose of examining the impact of average annual temperature, air humidity and daily temperatures on production properties, egg quality, productivity and egg weight various experimental research studies have been performed. The experiment was performed at the foot of the mountain Čemernik, at the Šurik Invest farm (municipality of Crna Trava), Republic of Serbia, in the period between May 1st, 2016 and August 31st, 2016. Geographical co-ordinates of the location are 42º44'06"N and 22º16'38"E, at an altitude of 1638 m.
At the experimental farm there are 25200 heads of theHISEX BROWN light line hen hybrid which produced 2.264.924 eggs in 123 days (May-August) whereby the average productivity was 74.28%.
Statistical data analysis was performed by calculating ambient humidity index and by applying various analytical models, was used SPSS statistical package together lith Student's *t*-test for data procesing and drawings showing the results without computation.

Results and Discussion

In May, during dry days, the THI was less than 74. Under such conditions average S class egg weight was 4.8 g, M class 8.3 g, L class 62.76 g, while average XL class egg was 22.35 g. In the course of this month average weight of cracked eggs was 1.75 g.

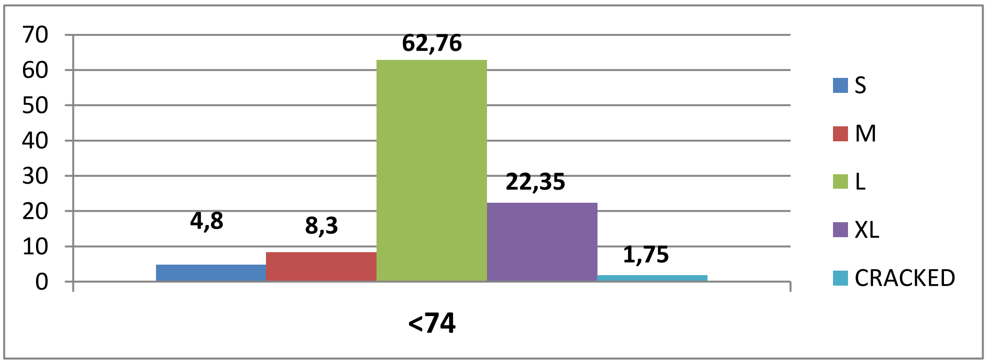

Chart 1: Egg weight per class depending on THI values in May

In June, THI values were expressed through three temperature intervals. Under the most favourable conditions, when THI value was under 74, average S class egg weight was 3.52 g, M class 4.93 g, L class 67.87 g, while XL class egg weight was 11.04 g. In this interval average weight of cracked eggs was 1.45 g.

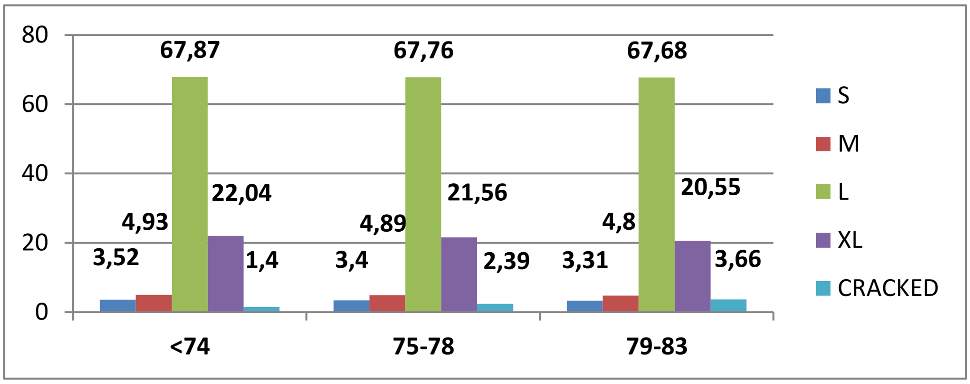

Chart 2: Egg weight per class depending on THI values in June

With the increase in temperature interval the egg weight per class decreased, whereby average egg weight in the temperature interval between 75 and 78 for S class was 3.4 g, for M class 4.89 g, for L class 67.76 g, while for XL class it was 21.56 g. With the increase in interval average weight of cracked eggs increased as well and it amounted to 2.39 g in this interval.
In the temperature interval between 79 and 83 laid eggs tended to lose on weight. Thus, average S class weight was 3.31 g, M class 4.80 g, L class 67.68 g, and XL class was 20.55 g. In this interval the weight of cracked eggs was 3.66 g.
In July, THI values were expressed through three temperature intervals. In the interval between 75 and 78 average S class egg weight was 3.74 g, M class 4.78 g, L class 68.48 g and XL class was 20.66 g. In this interval the weight of cracked eggs was 2.34 g.

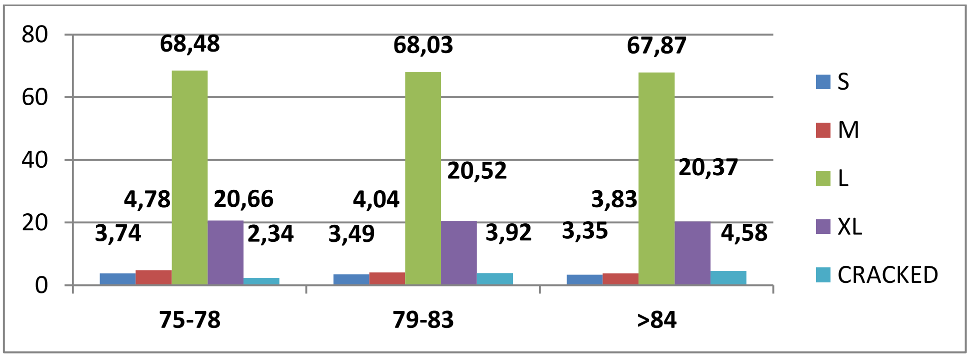

Chart 3: Egg weight per class depending on THI values in July

With the increase in temperature interval the egg weight per class decreased, whereby average egg weight in the temperature interval between 79 and 83 for S class was 3.49 g, for M class 4.04 g, for L class 68.03 g, while for XL class it was 20.52 g. With the increase in interval average weight of cracked eggs increased as well and it amounted to 3.92 g in this interval.
In the highest interval with average index values of over 84 laid eggs tended to lose on weight. Thus, average S class weight was 3.35 g, M class 3.83 g, L class 67.87 g, and XL class was 20.37 g. In this interval the weight of cracked eggs was 4.58 g.
In August, THI values were expressed through three temperature intervals. In the interval between 75 and 78 average S class eggsweight was 3.65 g, M class 6.92 g, L class 67.61 g, and XL class was 18.79 g. In this interval the weight of cracked eggs was 3.03 g.

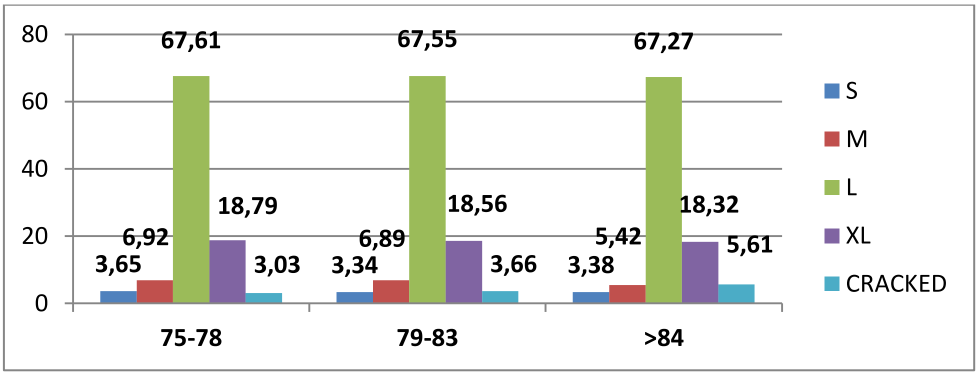

Chart 4: Egg weight per class depending on THI values in August

With the increase in temperature interval the egg weight per class decreased, whereby average egg weight in the temperature interval between 79 and 83 for S class was 3.34 g, for M class 6.89 g, for L class 67.55 g, while for XL class it was 18.56 g. With the increase in interval average weight of cracked eggs increased as well and it amounted to 3.66 g in this interval.
In the highest interval with average index values of over 84 laid eggs tended to lose on weight. Thus, average S class egg weight was 3.38g, M class 5.42 g, L class 67.27 g, and XL class was 18.32 g. In this interval the weight of cracked eggs was 5.61 g.

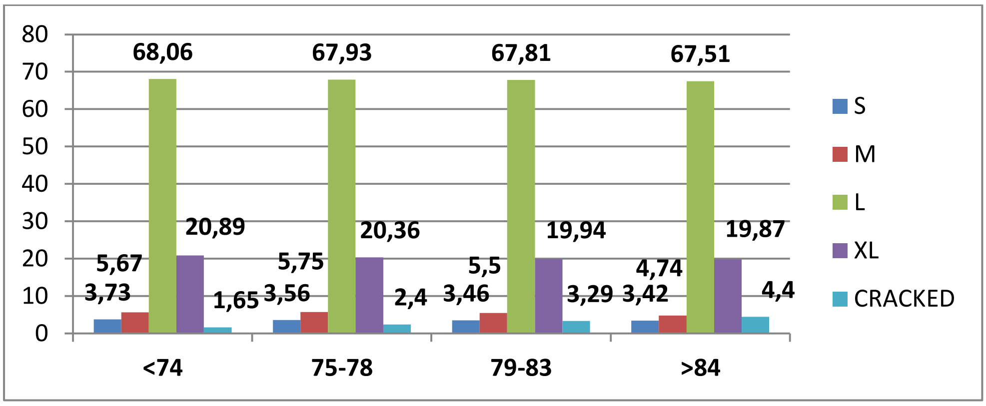

Chart 5: Egg weight per class depending on THI values in the period between May and August

Likewise, (Pešić *et al*., 2015) established that temperatures in poultry breeding facilities have the greatest impact on production results and animal health. Optimum temperature for mature poultry is between 19°C and 27°C. Temperatures higher than 28°C require that birds spend additional energy in order to cool down, which leads to heat stress. In the interval with maximum index over 84 average S class egg weight was 3.42 g, M class 4.74 g, L class 67.51 g, while XL class was 19.87 g. In this interval the weight of cracked eggs was 4.4 g.
Microclimatic conditions are a significant factor in egg production and in exploitation of laying hens, which is presented in Chart 2, where one can see the productivity interval for the observed period. With an increase in temperature over 21°C, egg production and average egg weight decrease. Furthermore, eggshell quality decreases due to lower calcium levels, which leads to eggshell cracking, described in the papers by Đukić *et al*.,(2009).
Hristov *et al.*,(2006) asserted in his paper that fighting heat stress was essential for farmers. He further asserted that the heat released by chickens was the greatest source of heat in the facility, whereby the negative effect of high temperature was enhanced in combination with high humidity. The damaging effect of high temperatures can be diminished primarily by constructing solid and insulated facilities, by installing quality equipment, and then by introducing quality nutrition and securing sufficient amount of clean and fresh water, which were the points of agreement in everyone´s research.

Conclusion

On the basis of the obtained results one can draw the following conclusions: With an increase in THI values the egg weight in all indexed intervals decreases. The largest egg weight is in the interval when there is no heat stress, i.e. when there is no THI change for a longer period of time. Such is the case with the month of May, when the interval has always been <74. Opposite to egg weight, cracked eggs weight increased with the increase in the interval which implies that high temperatures make the eggshell thinner. Thus, the largest weight of cracked eggs was in the interval with the greatest stress caused by an increase in THI values. This was especially conspicuous in the period when the stress was present for a longer period of time. The largest decrease in egg weight was observed in the heaviest class where the egg weight was decreased by an average of 1g, while in lighter classes the decrease in weight was less than 1g.

Abstract

Lactose is a major component of milk (typically around 5% of composition) that is not usually directly considered in national genetic improvement programs of dairy cattle. Lactose percentage and other traits of milk production in percentage may be used in indirect selection for health and fertility traits, which are economically important, but of low heritability. The aim to this study was to evaluate relation among percentage of lactose and others traits of milk production, somatic count cells and calving interval in selected breeding herds of Slovak Spotted dairy cows (S_0). A total of 16,334 control milk samples from 796 Slovak Spotted dairy cows born from 2001 to 2013 were used for estimation of parameters for percentage of lactose content (LC) and correlations with other milk yield (MY), somatic cell count (SCC) and calving interval (CI). These data were analysed using the Statistical Analysis System (SAS) version 9.3 and linear model with fixed effects: herds (H), years-season of control (YS), order of lactation (OL) and sire (S). By evaluation of milk yields we found out that the average of control samples of milk production during the examined period in all 16,334 control samples in 796 dairy cows were for lactose content 4.76±0.25%, 26.09±9.51 kgs of milk, 351.89±1,014.07 cells/ ml.10^3 of somatic cell count and 405.07±81.41 days of calving interval. The correlation among the traits of milk production, the somatic cells count and calving interval, for example lactose in % with milk in kgs, somatic cells count in cells/ml.10^3 and calving interval, was found as follows r = 0.45574, r = -0.29403 and r = -0.05025. These coefficients were statistically highly significant p <0.0001. The analyses by the effects on percentage of lactose (LC) reviled higher effect of sire R^2 = 0.158213 than effect of order of lactation R^2 = 0.082009. These effects were significant (P<.0001).

Keywords: *Slovak Spotted dairy cows, traits of milk, somatic cells count, calving interval, coefficient of determination.*

Introduction

Lactose is a major component of milk (typically around 5% of composition) that is not usually directly considered in national genetic improvement programs of dairy cattle (Haile-Mariam, Pryce, 2017; Costa et al., 2019). Lactose percentage and other traits of milk production in percentage may be used in indirect selection for health and fertility traits, which are economically important, but of low heritability (Satoła et al, 2017; Miglior et al., 2017). Costa et al. (2019) shows that lactose percentages has potentiality to be used as indicator trait to improve udder health in Fleckvieh dairy cows. Miglior et al. (2007) reported that lactose percentage was negatively genetically correlated with somatic cell score (-0.20) and may be used in selection for resistance for mastitis together with somatic cell score. Similar conclusions have been made by other authors such as Kasarda et al. (2015), Alessio et al., (2016), Bujko (2018b), Martin et al. (2019) and others. Some authors investigated the relationships between lactose percentage and fertility traits (Melendez et al., 2000; Martin et al., 2019). The contents of lactose in milk is influenced by multiple factors as are genetic and no-genetic (Alessio et al., 2016; Bujko et al., 2018a and others). The relationship of lactose percentage with production traits has been the subject of many studies (Ptak et al., 2012; Sneddon et al., 2015; Costa et al., 2018; Bujko et al., 2019). Factors affecting on lactose percentages shows in publications Alessio et al. (2016), Costa et al. (2019) and others. The aim to this study was to evaluate relation among percentage of lactose and others traits of milk production, somatic cell count and calving interval in selected breeding herds of Slovak Spotted dairy cows (S_0).

Material and Methods

The material for evaluation of milk components, somatic cells count and calving interval in selected breeding herds of Slovak spotted breed was provided from the database of Breeding Services of the Slovak republic.

A total of 16,334 control milk samples from 796 Slovak Spotted dairy cows born from 2001 to 2013 were used for estimation of parameters for percentage of lactose content (LC) and correlations with other milk yield (MY), somatic cell count (SCC) and calving interval (CI).

We divided dairy cows only breed-type S_0 - cows with genetic proportion of pure Slovak Simmental blood into 87.5 % and divided dairy cows by order of lactation the "I" - the first, "II"- the second, "III"- the third, "IV"- the fourth, "V"- the fifth and higher lactation.

The basic statistical and variability characteristics (least square means, standard deviations) were evaluated using the Statistical System (SAS) version 9.3 (TS1M2) Enterprise Guide 5.1 (SAS, 2011). The mixed procedure was used for the final analysis. The value of statistical significance (P), the value of the F-test and the coefficient of determination (R^2) of the above mentioned of milk components, somatic cell count and calving interval were evaluated with its relation to: herd, year and season of controls, order of lactation and sire.

For actual computation a linear model with fixed effects was used:

$$y_{ijklm} = \mu + H_i + YS_j + OL_k + S_l + e_{ijkl}$$

, where: μ = mean value of depended variable, H_i = fixed effect of herd (1 - 5), YS_j = fixed effect of years-season of control (1 - 34), P_k = fixed effect of order of lactation (1 - 5), S_l = fixed effect of sire (1 - 81), e_{ijkl} = residual error.

Statistical evaluations of the differences between traits were tested at the levels of statistical significance: $^{+}$P<0.05, $^{++}$P<0.01, $^{+++}$P<0.001 or $^{-}$P>0.05.

Results and Discussion

The basic traits of lactose content (LC), milk (MY), somatic cell count (SCC) and calving interval (CI) are presented in Table 1. The mean of LC, MY, FC, PC, SCC and CI in selected herd of Slovak Spotted dairy cows were similar to the national average for evaluated traits dairy cows in Slovak Republic (The Breeding Service of the Slovak Republic. S.E., 2016).

Table 1. Statistical characteristic of LC, MY, FC, PC, SCC and CI in dairy cows of Slovak Spotted cattle

Traits	**Statistical parameter**					
	n[1]	$\bar{x}$ [2]	**SD**[3]	**CV**[4]	**MODE**[5]	**MEDIAN**[6]
Lactose in (%)	16,334	4.76	0.25	5.34	4.68	4.80
Milk in (kg)		26.09	9.51	36.47	29.3	26.2
Fat in (%)		4.06	0.73	18.03	3.81	4.03
Proteins in (%)		3.59	0.36	10.13	3.54	3.58
SCC in (ml^{-1} x 10^3)		351.89	1,014.07	288.18	21.0	99.0
Calving interval in (day)		405.07	81.41	20.1	342.0	385.0

[1]number of observation, [2] mean, [3]standard deviation, [4]coefficient of variation, [5]mode (value that appears most often in a set of data), [6]median (value separating the higher half from the lower half of a data sample)

By evaluation of milk yields we found out that the average of control samples of milk production during the examined period in all 16,334 control samples in 796 dairy cows were for lactose content 4.76±0.25%, 26.09±9.51 kgs of milk, 351.89±1,014.07 cells/ ml.10^3 of somatic cell count and 405.07±81.41 days of calving interval. The mean of lactose content (4.76 %) was comparable in this study than that reported in literature (4.49%–5.09%, Welper and Freeman, 1992; Sneddon et al., 2015 and Satoła et al., 2017). These results are similar with conclusions as Miglior et al. (2007), Bujko (2011), Løvendahl and Weisbjerg (2017), Costa et al. (2018) and others.

Table 2. Relation between LC and other traits (MY, SCC and CI)

Traits	**Milk in kg (MY)**	**Fat in % (FC)**	**Proteins in % (PC)**	**Somatic cell count (SCC)**	**Calving interval (CI)**
Lactose in % (LC)	0.45574^{+++}	-0.15658^{+++}	-0.34094^{+++}	-0.29403^{+++}	-0.05025^{+++}

$^{+++}$ P<0.001

The correlation among the traits of milk production, the somatic cells count and calving interval, for example lactose in % with milk in kgs, fat in %, protein in %, somatic cells count in cells/ml.10^3 and calving interval, was found as follows r = 0.45574, r = -0.15658, r = -0.34094, r = -0.29403 and r = -0.05025. These coefficients were statistically highly significant p <0.0001. These results are correspondence with Melendez et al. (2000), Haile-Mariam and Pryce (2017), Bujko et al. (2018a), Martin et al. (2019) and others. Miglior et al. (2007) shows correlation coefficients among LC with SCC (r_p= -0.23, r_g= -0.2), than Sneddon et al. (2015) among LC with SCC (r_p= -0.19, r_g= -0.07).

Table 3. Factors affecting of lactose contents (LC) in Slovak Spotted dairy cows (S_0)

Sources of variability	**DF**[1]	**Mean Square**	**F Value**	**Pr> F**	**R-Square** [2]
					Lactose contents
Herd (H)	4	4.17442983	65.47	<.0001	0.015784
Years-season (YS)	34	1.84745117	30.21	<.0001	0.057631
Order of lactation (OL)	5	21.68854719	364.69	<.0001	0.082009
Sire (S)	81	2.0920902	38.18	<.0001	0.158213

[1] degrees of freedom, [2] coefficient of determination (R^2)

The linear model to represent coefficients of determination on lactose contents with all fixed effects R^2 = 0.215936 %. These effects were significant (P<.0001). In Table 3 showed the analyses by the effects on percentage of lactose (LC) reviled higher effect of sire R^2 = 0.158213 than effect of order of lactation R^2 = 0.082009. These effects were significant, P<.0001 (Table 3). These results are similar with results Alessio et al. (2016), Tančin et al. (2018), Costa et al. (2019) and others. Alessio et al. (2016) shows that the lactose content in milk is influenced by somatic cell count, parity, and season.

Conclusions

In conclusion, correlation between lactose in % with milk in kgs was medium high positive. Correlations between lactose in % and somatic cells count in cells/ml.10^3 as well as lactose in % and calving interval were found low negative. The analyses by the effects on percentage of lactose (LC) reviled higher effect of father than effect of order of lactation.

Abstract

The aim of the experiment was to evaluate growth ability of Aberdeen angus calves breed in organic farming system in the area of White Carpats (southeastern part of Czech Republic). Total number of animals used in experiment was 181 – 82 bulls and 99 heifers. Evaluation of growth ability was made according to methodology of Czech Beef Breeders Association. Average birth weight of calves was 37 ± 3.18 kg. Bulls had significantly ($p<0.01$) higher birth weight (39 ±3.72 kg), than heifers (36 ± 2.53 kg). In the age of 120 days there was significant difference ($p<0.01$) between gender at the range of 14 kg in favor of bulls (187 ± 30.42 kg). In the age of 210 days differences between sexes deepened even more. Average weight of bulls was 280 kg and of heifers was 257 kg. Same growth trend was also maintained at the age of 365 days, when difference ($p<0.01$) between bulls and heifers was 79 kg. Mean value of daily gain of bulls, from birth to 365 days, was 1424 $g.day^{-1}$, of heifers was 943 $g.day^{-1}$. In the age of 210 days hip height was also measured. Between gender there were no significant ($p>0.01$) differences.

Keywords: *Aberdeen Angus, growth of calves, bulls, heifers*

Introduction

Breeding meat livestock breeds is a dynamically developing sector in the Czech Republic. At present, 222,000 pieces of cows of beef cattle breeds are raised in the Czech Republic according to the Czech Statistical Office. The Aberdeen Angus (AA) breed is the second most numerous beef cattle breed (the efficiency inspection includes 4022 pieces of cows). Bures et al. (2004) evaluated slaughter parameters of bulls of the AA, Hereford, Charolais and Meat Simental breeds. Results confirmed a higher growth intensity in the group of breeds with a large body frame (Charolais, Meat Simental), while animals of the medium frame (AA and Hereford) were rather characterised by a higher beef quality. Mazzucco et al. (2016) states that the breed is highly adaptable and suitable for raising in most continents of the world. According to Gregory and Cudiff (1980) this breed is ideal both for pure-bred breeding, and for utility cross breeding with numerous domestic cattle breeds. This statement is supplemented by French et al. (2000); Garcia et al. (2008) and Dinh et al. (2010) who point out, in addition to the high growth ability of AA, an excellent quality of slaughter treated body and meat. The authors particularly advise of the representation of fatty acids and their positive effect on the human health. Hornick et al. (2000) point out excellent growth abilities of the breed when individuals achieve a high compensatory growth after the period of insufficient quantity or worsened quality of the grazing area. Bown et al. (2016) compared a growth ability of the bulls of Holstein cattle, AA and Hereford breeds, where the authors did not prove a statistically significant differences ($p<0.05$) in growth intensity among the breeds. However, Schenkel et al. (2004) advise of the difference in the composition of the slaughter body in individual cattle breeds. In the Czech Republic, the evaluation of the growth of beef cattle is carried out according to the Methodology of animal recording beef Efficiency Inspection of Cattle without Market Milk Production, issued by the Czech Beef Breeders Association. The methodology is in compliance with the rules International committee for

animal recording. Appointed person determines a birth weight of calves and a weight at the age of 120, 210 and 365 days.
The goal of this experiment was to compare the growth intensity of bulls and heifers of the AA breed raised in the organic farming system.

Material and methods

The experiment was carried out at a farm operating in the area of the White Carpathians in the southeaster part of Czech Republic. Since 2006 the farm has been certified for the ecological management system focused on breeding beef cattle and production of oats and hay. The total area of the farm consists of 272 ha of meadows and 12 ha of arable soil. The farm is situated at the altitude from 380 to 560 m above he sea level. The farm raises the AA breed, where the basis herd consists of 200 pieces of cows of the black and red colour (an approximate ratio of 1 : 1). The reproduction of breeding cows is ensured by a combination of natural reproduction and insemination. The farm uses the system of seasonal calving from the middle of January to the end of March. Most deliveries occur in the wintering grounds. The pastoral period start at the end of March and runs until the end of November. Calves are not additionally fed by grain fodder. Animals have a mineral lick available at the pasture and they have an unlimited access to water. Outside the pastoral period animals are stalled in the wintering grounds in separates stables for bulls, heifers and cows. All stables use a deep bedding. Hay, grass ensilage, mineral lick and water are used for feeding ad lib. The growth intensity was evaluated according to the "Methodology of Efficiency Inspection of Beef Cattle Breeds" issued by the Czech Beef Breeders Association that is authorised by the breeding activity of beef cattle bred in the Czech Republic. Total number of animals used in experiment was 181 – 82 bulls and 99 heifers. During the experiment, the birth weight and the weight at 120, 210 and 365 days of calves' age was determined by weighing on a stationary cattle scale with a built-in weight indicator. An average daily increment was calculated from the detected weights from the birth up to 120 days, from 120 to 210 days, from 210 to 365 days and from birth to 365 days of the age of animals.
In addition to the weight, the sacrum height was determined at the age of calves of 210 days. Measurements were performed using a Lydtin's measuring rod.
The data statistical analysis was carried out using the STATISTICA 12.0 statistical software using the ANOVA method:

$$Y_{ij} = \mu+G_i + e_{ij}$$

where:

μ = dependent variable
G = gender (bull, heifer)
e = residue

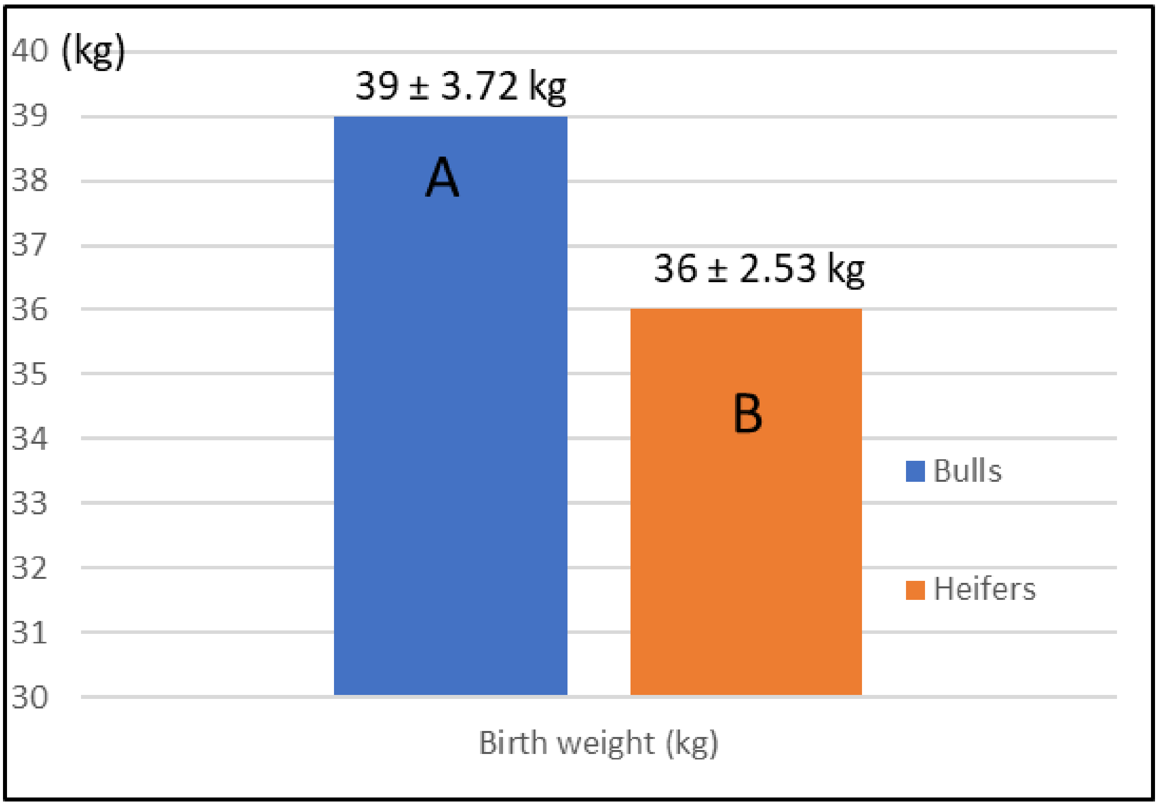
Differences between gender were compared using Tukeyś post-hoc test.

Results and Discussion

An average birth weight of the newborn calves was approximately 37 kg with a difference of ± 3.18 kg (Fig. 1). A statistically provably higher ($p<0.01$) birth weight was determined in bulls (39 ± 3.72 kg) compared to heifers (36 ± 2.53 kg). Casas et al. (2012) confirmed our results in their research stating that bulls have a higher birth weight compared to heifers. Bormann et al., (2006) specify birth weights of heifers of the AA breed raised in the U.S.A. of 34.9 kg, which corresponds to our results. In contrast, Berger et al., (1992) published birth weights of heifers only of 30 kg. An average calf weight at the age of 120 days was 178 kg with a difference of ± 28.05 kg, where bulls reached an average weight of

187 kg (Fig. 2). The weight of heifers at the same age was determined to be 14 kg ($p<0.01$) lower (173 ± 25.56 kg).

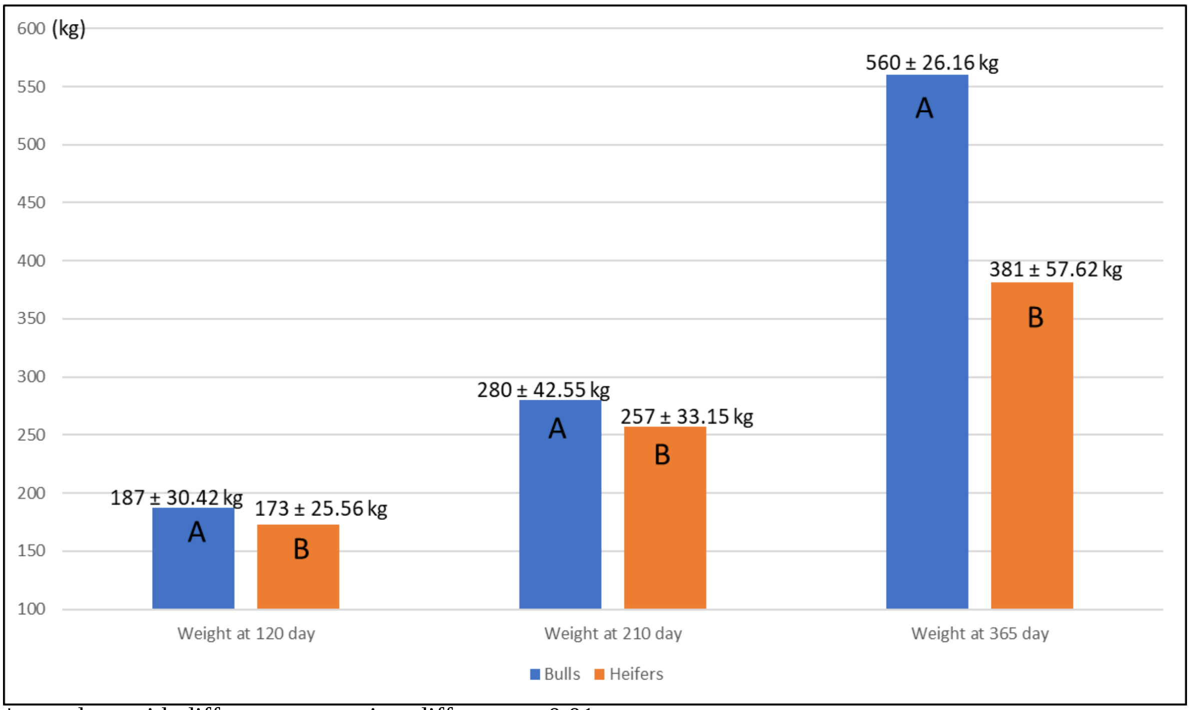
Fig. 1 Birth weight of calves



*A, B values with different superscripts differ at $p < 0.01$
** LSM ± S.D.

At the next measurement within the efficiency inspection at 210 days of animals' age, average weights of animals detected were 265 kg, when even more significant ($p<0.01$) difference was proven between genders compared to the previous weighing. Heifers reached the weight of 257 ± 33.15 kg. Bulls reached the weight of 280 ± 42.55 kg. Variability between individuals also occurred within both genders. This relates to the effect of individuality of every animal to their own growth ability which is intensively manifested at this age of animals because the effect of mother has been ceasing (ending of lactation). Our results correspond to the data specified in the paper of Casas et al. (2012) who evaluated offspring of beef cattle breeds. Significantly lower weights of bulls (204 kg) and heifers (192 kg) at the age of 200 days were published by Gregory et al. (1991). At the age of 210 days the hip height was determined in both genders, which ranges in the variation range from 116 to 138 cm (Fig 4). The hip height was inconclusively ($p>0.05$) determined for bulls of (128 ± 9.27 cm. A significantly lower values of the hip height were published by Gregory et al. (1991), when the authors specified the hip height for bulls of 117 cm and for heifers of 113 cm. Only 97 animals were evaluated at the next weighing at 365 days of age (50 bulls and 47 heifers). The reason for evaluating a lower number of animals was the fact that at the end of the pastoral period a part of animals were sold due to capacity reasons. An average weight of one year-old animals was determined of 444 kg, and bulls reached the weight of 560 kg ± 29.16 kg, while heifers weighted only 381 ± 57.62 kg. A statistically provable ($p<0.01$) difference between the genders was also proven in this weighing.

Fig. 2 Effect of gender on growth of calves



*A, B values with different superscripts differ at $p < 0.01$
** LSM ± S.D

Average daily increments in calves in the period from birth to 120 days were in the amount of 1168 kg with a difference of ± 227 g.day^{-1} (Fig. 3). A significantly higher growth intensity in this period was proven in bulls (1232 ± 244 g.den^{-1}). In the period from 120 to 210 days a decrease of the growth intensity was registered in both genders, caused especially by the end of mother's milk and a transfer to the full plant fodder. An average daily increment of bulls was calculated to be 1039 ± 274 g.day^{-1} (a decrease in the growth intensity by approximately 100 g.day^{-1}). The decrease in heifers was almost by 200 g.day^{-1} (936 ± 265 g.day^{-1}). The growth intensity of females was continuously decreasing with the increasing age. In the period from 210 to 365 days of age an average daily increment was 708 ± 292 g.day^{-1}. In contrast, the trend was opposite in bulls. In the period from 210 to 365 days of age the bulls reached the highest growth intensity (1580 g.day^{-1}). Overall, it can be stated that in the period from birth to 365 days of the age of bulls put on weight significantly ($p<0.01$) faster (1424 ± 278 g.day^{-1}) than heifers (943 ± 157 g.day^{-1}). Similar values of average daily increments in bulls were published by Albertí et al., 2008; Bures and Barton (2018).

Conclusions

The goal of this experiment was to compare the growth intensity of bulls and heifers of the AA breed raised in a farm managed at the ecological agricultural regime. A higher birth weight and a higher growth intensity of bulls in the period from birth to 365 days of age was confirmed. The difference of 179 kg between the weight of bulls and heifers was proven at 365 day ages. The growth intensity of heifers was highest in the period from birth to 120 days of age and then there was a linear decrease of average daily increments. On the other hand, the growth intensity of bulls was highest in the period from 210 to 365 days of age. No significant differences were proven in the evaluation of growth to the height of sacrum between cattle genders at 210 days age. It can be stated according to the reached results of the growth intensity of bulls and heifers that this breed is suitable for breeding under conditions of the Czech Republic; animals are also able to reach adequate growth ability in ecologically managed farms.

Abstract

The aim of the study was to examine the effect of different dietary protein content on the production parameters of cross-bred fattening lambs. The study was conducted on 20 cross-bred lambs from different Pramenka types, divided in two groups. The lambs were at the age of 55 - 60 days, and the fattening period lasted five weeks. The first group of lambs were fed with a mixture of cereals and sunflower meal that contained 12.26% of crude protein, while the second group was fed with a concentrate mixture with crude protein level of 14.69%. During the fattening period the lambs from both groups were fed with hay ad libitum. Fresh water was offered with no restriction during the study. Lambs were weighed at the starting and at the end of every week of the study, and the results were statistically analyzed. The body weight gain was determined within the both groups according to age of lambs during fattening. At the end of fattening period higher average weight and weight gain with no significance ($p>0.05$) were observed in lambs fed with a mixture of cereals and sunflower meal. However, similar values were determined for feed to gain ratio in both groups of lambs. The obtained results indicated that the cross-bred fattening lambs fed with a mixture of cereals and sunflower meal had achieved better, but not significantly better production parameters that may have economical benefit for lamb meat production.

Key words: *lamb, feed mixture, production parameters, fattening*

Introduction

Sheep breeding in Bosnia and Herzegovina generally plays an important role from an economic, cultural, and environmental point of view. Breed structure is quite varied although it is dominated by indigenous breed Pramenka that has a large number of strains of different phenotypic and breeding characteristics. Pramenka, like the rest of the sheep, belongs to a group of sheep of combined production qualities. The economic significance of the breeding of pramenka is based on their biological characteristics, which enable the relatively scarce vegetation of pastures to turn into highly valuable products: meat, milk, wool. Production of lamb meat in Bosnia and Herzegovina is important for the nutritional needs of the local consumers.

The quantity and quality of the lamb meat is strongly influenced by the genotype, sex, age, body weight at slaughter and numerous other non-genetic factors (Ružić-Muslić *et al*., 2005; Mioč *et al*., 2007; Petrović *et al*., 2009). In order to increase production and quality of meat are carried out different types of crossing local sheep with imported noble breeds. There are numerous references on fattening and slaughter traits of different sheep crosses and mostly they have better production parameters (Konyves *et al*., 2014; Petrović *et al*., 2015). However, Kozarovski *et al.* (2000) reported that crossing the merino type Ovčepoljska sheep and Merinolandschaf did not give expected results regarding birth body weight, daily weight gain and slaughter traits.

Nutrition is one of the most important factors that influence the growth of lambs during the fattening and it depends on the type of breed, rearing system and management strategy. Sheep

are the most efficient converters of the hilly-mountain vegetation into high quality animal protein. Fattening of early weaned lambs lasts short and provide good meat quality using hay and cereals or concentrate mixture.
The aim of the study was to examine the effect of different dietary protein content on production parameters of cross-bred fattening lambs.

Materials and Methods

The study was conducted on 20 cross-bred lambs of Dubska and Sjenica Pramenka. The lambs were divided into groups and they were 55 – 60 days old at the start of the experiment. The fattening period lasted five weeks. During the experiment the first group (Group I) of lambs were fed with a mixture of cereals (corn, barley and wheat bran) and sunflower meal with no mineral-vitamin premix that contained 12.26% of crude protein, while the second group (Group II) was fed with a concentrate mixture for older lambs with 14.69% crude protein. The lambs from both groups during fattening were fed hay *ad libitum*. The chemical analysis of cereals mixture, concentrate mixture and grass hay are presented in Table 1.
The body weight and cereals and concentrate mixture consumption of lambs were recorded weekly during the trial period. The body weight gain was calculated weekly. Feed consumption and feed to gain ratio were calculated at the end of the fattening period (5th week).
The obtain results were statistically analysed using Microsoft Excel 2010, module Data Analysis by the t-test.

Table 1. Chemical composition of cereals mixture, concentrate mixture and hay (as-fed)

Nutrients, %	Cereal mixture	Concentrate mixture	Grass hay
Dry matter	87.29	87.71	86.95
Crude protein	12.26	14.69	8.02
Crude fiber	6.87	5.88	27.64
Crude fat	3.52	3.35	1.42
Ash	3.94	4.81	7.41
Calcium	0.64	1.00	0.86
Phosphorus	0.52	0.62	0.18

Results and Discussion

Body weight, weight gain, feed consumption and feed to gain ratio are presented in Table 2.
The results of this study show that the lambs fed mixture of cereals (corn, barley and wheat bran) and sunflower meal with no mineral-vitamin premix (Group I) achieved higher body weight and average daily weight gain compared to group II (lambs fed with concentrate mixture for older lambs) with no significance ($p>0.05$). The average body weight of lambs obtained in our research is in accordance with the results that have been conducted on cigaja breed lambs in organic breeding and during the fatteing lambs were fed mixture of grain and alfalfa hay *ad libitum* (Antunović *et al.* 2010). The results of Softić *et al.* (2017) indicated that lambs fed with cereals mixture and sunflower meal achieved better with no significance ($p>0.05$) all linear body measures comparing to lambs fed with feed mixture.

Table 2. Growth performance of lambs during fattening period

Parameter	Group I	Group II
Body weight (kg)		
Initial	18.90	18.40
1st week	20.50	19.80
2nd	22.20	21.50
3rd	24.10	23.40
4th	25.80	25.00
5th	27.20	26.40
Daily weight gain (g)		
1st week	232.86	208.57
2nd	237.14	241.43
3rd	278.57	268.57
4th	231.43	232.86
5th	207.14	194.29
Average	237.43	229.14
Feed consumption, mixture (g/day/head)	785.43	779.86
Feed to gain ratio, mixture (g/g)	3.31	3.36

Group 1 – group fed with mixture of cereals
Group 2 – lambs fed with feed mixture

Marić *et al.* (2013) conducted similar research on lambs breed Dubrovačka ruda using feed mixture with 16% protein and corn with wheat bran. The lambs fed with feed mixture obtained higher body weight and average daily gain compared to group fed with corn and wheat bran without significance ($p>0.05$) but these results are lower than in our study (both tested groups achieved higher body weight and average daily gain). In the study that was conducted by Dabiri and Tonney (2004) there was little difference in average daily gain or feed efficiency between lambs fed the diets with 15 or 17% CP, suggesting that a crude protein level near 15% based on supplemental soybean meal would be optimal for 25- to 40-kg growing Finnsheep × Dorset lambs.
Body weight (28.87 kg) of lambs breed Lička Pramenka before slauthering at average age of 158 days (Kaić *et al*. 2011) and is similar to results that reporeted by Bedeković *et al.* (2007) for lambs Travnička pramenka at age of 3,5 months (28.05 kg). The results of both researches are in agreement with our results obtained on crooss-bred lambs of Pramenka (27.20 and 26.40 kg). These results show influence of breed and age of lambs on body weight.
The average daily gain of lambs from Group I were 237.43 g and 229.14 g from Group II and these results are very similar with other authors experiment data (Zervas *et al.,* 1999; Softić *et al*., 2002; Ramljak *et al.,* 2005). Cmiljanić *et al*. (2003) reported higher average body weight gain (299 g and 251 g) during the all period of fattening in cross-bred lambs of Pirot Pramenka and Wurttenberg in semi-intensive and extensive feeding system, respectivelly. However, several authors (Kozarovski *et al*., 2000; Kaić *et al.,* 2011; Marić *et al*., 2013) have

reported lower daily weight gain in fattening lambs comparing with the results obtain in our study.

Based on the results of the cereals and feed mixture consumption, it is evident that lambs of Group I and Group II consumed almost the same amount of feed/day/lamb (785.43 and 779.86 g, respectivelly) during the fattening (differences < 1%) and calculated feed to gain ratio were similar in both groups (3.31 and 3.36) that is in agreement with the results of Softić *et al.*, (2002).The results suggest that the gain weight and feed to gain ratio are satisfactory for used diet in fattening and could be useful in futher breeding operation for producing a domestic lamb meat.

Cmiljanić *et al*., (2003) reported that the lambs in semi-intensive feeding system consumed 15.09 % hay less and 10.94 % less concentrate for unit of gain in comparison with lambs in extensive feeding system. Onk et al. (2016) were conducted the study for the purpose of comparing male Tuj lambs fed under extensive, semi-intensive and intesive fattening condition. Lambs in the extensive group were grazed in pasture. In addition to pasture, concentrated feed was given to lambs in the semi-intensive group. At the end of 90 days of fattening period the result show that the lambs of semi-intensive group obtained higher body weight 41.22 kg, and average daily gain 229.66 g compared to group of extenisive and intensive groups (body weight were 31.19 and 40.56 kg, respectivelly and average daily gain were 117.52 and 221.11 g, respectivelly. The results are in agreement with our results that lambs could obtained higher body weight even if they fed with lower amount of concentrated feed (200 g vs. 400 g in intensive groupFood conversion ratio was in favor of lambs kept indoors in individual pens and fed 200 g of hay/lamb/day and concentrates ad libitum (10.75 vs. 6.52 kg DM/kg BW gain) comparing to lambs kept on pasture, but feeding and labor costs were in favor of lambs of kept on pasture (Zervas *et al.*,1999), and author concluded that the system of fattening lambs on pasture can allow for a higher margin to the farmer because of the lower inputs and the products of higher value, compared to the indoors fattening system.

Conclusion

Results obtained in this study indicate that cross-bred lambs of Dubska and Sjenica Pramenka fed with a mixture of cereals (corn, barley and wheat bran) and sunflower meal with no mineral-vitamin premix that contained 12.26% crude protein can achieve better, but not significantly better production parameters that could have beneficial effects for economical lamb meat production with traditional character.

Abstract

The researches of radioactivity in poultry feed are particularly important because a part of the quantity of radionuclides in the food that animals ingest could be transmitted to people by means of the path of radionuclides in the food chain.

The study was conducted in order to detect the natural radioactivity in poultry feed and its values were compared with the measured values with poultry feed which is being produced in other parts of the world. The samples were analyzed by means of an instrument – gamma spectrometer (Canbera Packard) with a high purity germanium detector. The measurement was performed in a hermetically sealed container, whereby the spectra obtained from the measurement were analyzed by using the program GENIE 2000.

The results showed that the activity concentrations in feed supplements are within the range from 59.6 to 127.4 Bq/kg for 40K, 12.7 to 18.5 Bq/kg for 226Ra and 4.6 to 11.7 Bq/kg for 232Th, while those of the compounded feed are within the range from 64.7 to 172.0 Bq/kg for 40K, 9.7 to 29.4 Bq/kg for 226Ra, and 19.6 to 42.1 Bq/kg for 232Th. As it was expected during the analyses, the obtained values for the compounded feed were higher than the values for the feed supplements, which is expected, since some of these supplements are used for compounding feeds. In addition, anthropogenic radionuclides were not detected which shows that there was no contamination due to artificial radionuclides. The values of the specific activity obtained in this study do not exceed the safety limits, emphasizing the insigificant danger of radiation that arises from the Earth's radionuclides that are naturally present.

Key words: gamma spectrometry, feeds, natural radioactivity.

Introduction

Animal feed is developed from an organic basis (plants or animals) and is intended to provide the fullest diet possible (Filho et al., 2016). Very often, in order to improve the nutritional value of animal feed, it is supplemented with substances that could increase the level of activity of radionuclides.

In Macedonia, the most commonly used poultry feed is soybean, maize and "Premix Vitamínico Mineral", a bone meal and a fish meal. Therefore, control of radionuclides of these specimens is required, especially in phosphate stone, which is another raw material used in the production of animal feed additives (Casacuberta et al., 2010), which provides calcium for domestic animals such as poultry. One of the most common ways in which radionuclides reach poultry is ingestion, that is, consumption of foods that may contain a specific level of radiation, which would impose concerns in regard to such used poultry feed.

Considering the fact that through the food chain radioactive substances reach the human, more attention has been paid to these problems in the last decades in terms of the radiation safety of the population.

People consume eggs and poultry meat, therefore it is expected to monitor the levels of radiation in poultry feed, because a part of the amount of radionuclides in the food that

animals ingest could be passed on to people through the path of radionuclides in the food chain (Mc Donald et al., 1999; Breuninger et al., 2002; Hernandez et al., 2004). For this reason, due to the transfer of radioactive substances from the environment to agricultural, livestock and fish products, radioactive contamination of food and its health effects have become a major concern for people (Ramasany et al., 2006; Kaplan et al., 2011).
The study was conducted in order to detect natural radioactivity in poultry feed and the results were compared with measured values of poultry feed produced in other parts of the world.

Material and methods

2.1 Sampling

The poultry feed samples were taken from several producers, and several samples were directly purchased from the market in Macedonia. All samples were homogenized in a blender and then placed in Marinelli (hermetically sealed containers with a weight of approximately 450 grams).
The Marinelli were stored for 10 days in order to achieve a balance of radium and thorium with their daughters.

2.2 Instrument

The spectral analysis of the radionuclides of these samples was conducted by applying a γ-ray spectrometer with high purity germanium (HPGe) detector with 30% relative efficiency and energy resolution (FWHM) of 1.8 keV for 1.33 MeV reference passage of ^{60}Co (Verdoya et al., 2009).
The detector was protected with 9cm-thick lead with an internal line with a 0.5 cm-thin copper panel covered by 1 mm aluminum in order to absorb the x-rays from the lead and the copper. The internal size of the cavity of the shell was 30 x 30 x 30 cm. The detector was given a high voltage through a preamplifier which was then connected to an amplifier with a computer based channel analyzer through an ADC (analogue to digital converter). The software used for obtaining the data is Canberra software package Genie-2000, including search of maximal value and modules for identification of nuclides. The system was regularly calibrated for energy and efficiency. The gamma rays of interest were within a range of 50-3000 keV. The prepared Marinelli glasses (samples) were placed on a final detector at a distance of approximately 10 mm. Every sample was measured within a period of around 62000s in order to get good statistics and the constant time was lower than 10%. The measurements with an empty Marinelli glass, in identical conditions were also conducted in order to determine the basic recounts. Then they were deducted from the measured spectrums of every sample in order to obtain the net activities of the radionuclides.

Results and discussion

The activity concentrations of ^{40}K, ^{226}Ra and ^{232}Th were assessed and they were shown in Table 1 and Table 2 as well as in Figure 1 and Figure 2. The results showed that the activity concentrations in feed supplements range from 59.6 to 127.4 Bq/kg for ^{40}K, 12.7 to 18.5 Bq/kg for ^{226}Ra and 4.6 to 11.7 Bq/kg for ^{232}Th, while that of the compound feed range from 64.7 to 172.0 Bq/kg for ^{40}K, 9.7 to 29.4 Bq/kg for ^{226}Ra and 19.6 to 42.1 Bq/kg for ^{232}Th.
Compound feed had higher values than poultry feed supplements, which is expected, because some of these supplements are used for combining the food. The results on the natural radioactivity were compared with the results from different countries of the world and were relatively higher compared to other such studies (Harb et al., 2010; Filho et al., 2016).
Presence of anthropogenic radionuclides was not found, which shows that there is no contamination due to artificial radionuclides.

Conclusion

The values of the specific activity in this study did not exceed the safety limits, emphasizing the insignificant radiation hazard arising from naturally occurring earth radionuclides.

The results were compared with other poultry feed in other parts of the world, which shows that at the present level of radioactive contamination, there would be no need to take measures related to the reduction of radioactive contamination. The conclusion in this study is that the transfer of such levels to poultry meat and, ultimately, to the human, in the path of radionuclides, will not pose a danger when the public will eventually consume the meat and eggs from the poultry that consume such feed.

Abstract

The aim of this study was to evaluate the carcass and qualitative parameters of veal from Holstein bull calves - two groups of 10 calves each. Calves of the 1st group received a basal diet (milk replacer and concentrate) for the first stage of experiment (60 days). Then, they received feed mixture (maize silage, alfalfa silage, concentrate). The 2nd group was during whole experiment fed with the milk replacers and the starter concentrate, while after 35 days, liquid milk was replaced with pellets form. Calves were slaughtered after about 4 months.The 1st group of calves had higher slaughter weight ($P<0.05$), but lower dressing percentage ($P<0.05$). Significantly higher proportion of kidney fat ($P<0.05$) exhibited calves of the 2nd group. No significant, but higher proportion of meat from right-half carcass was revealed in the 2nd group. Contrariwise, right-half carcasses of 1st group had higher proportion of bones and separable fat ($P>0.05$). According to the CIE colour scale of MLT measured 24 hours *post mortem*, calves of the 1st group had darker (lower L^*; $P>0.05$) and redder (higher a^*; $P<0.05$) meat. The MLT from calves of 1st group had higher pH_{24} value ($P<0.05$), electrical conductivity ($P>0.05$), but lower drip loss value ($P>0.05$). Chemical composition of MLT showed higher moisture content ($P<0.05$) in the 2nd group of calves. No significant differences in protein and intramuscular fat content were revealed. We found minimal differences in WB shear force between monitored groups ($P>0.05$).

Introduction

For a modern consumer, the taste and nutritional value of the meat are two important quality traits. The tendency is to focus on producing consumable lean meat with minimal excess of visible fat (Webb and O'Neill, 2008). Traditionally, many European consumers include veal to the highest quality. Such meat is associated with a healthy product, low fat content and smooth, delicate taste (Vieira *et al*., 2005). Dairy calves for the meat production are generally separated from the cows at birth, receiving a nutritionally balanced feed. In most cases, these calves are a by-product of dairy farms (Fluharty *et al.*, 2000). The consumer may also define a required feeding system, however, that must comply with applicable country-specific regulations. In general for veal production may be used suckling (*mother-fed*), milk replacers (*formula-fed*) or combinative feeding, which may include whole milk, milk replacers, silage, cereals, grains or other plant products. Under the legislation of specific EU member States, feed should not contain fishmeal, animal origin supplements, growth promoters or products derived from genetically modified organisms (UNECE, 2011). In terms of animal health and welfare, it is important for veal producers to optimize the growth of rosé calves after weaning. In particular, a fluent weaning from liquid dairy feed mixtures to solid feed is required, as

well as its effective utilization, which is mainly influenced by management before weaning and after weaning (Drake, 2017). Feeding with milk and concentrated solid feed could affect the utilization of nutrients in the feed, especially at an early age of animal when microbial fermentation and rumen development is restricted (Brscic *et al*., 2014). Several articles describe systems of early weaning from liquid milk replacers and its replacement with granulated milk (Terré *et al*., 2016; Fletcher, 2016). In general, the positive impact of this method (mainly on heifers) on growth, increased intake of solid feed and health status is described, which allows to increase of milk production in the next generation of dairy cows.
The aim of this work was to verify a modified feeding method of calves with granulated dairy feed mixture in the Holstein bulls and its influence on meat production and quality compared to traditionally fed calves.

Material and methods

For this experiment bull calves from Holstein breed (n = 20) were studied. Calves were born within a week. Calves were housed in individual outdoor crates and divided into two groups with different diet. Calves of the 1st group received a basal diet (liquid dairy feed mixture and starter feed mixture) for the first 60 days. From 60 days to 75 days they were gradually adapted to solid feed mixture. Calves were fed with dairy feed mixture once per day, starter feed mixture *ad libitum* and total mixed ration (TMR) in small amount. After this stage they were fed with the feed mixture (maize silage, alfalfa silage and concentrate) ad libitum; drinking water was available ad libitum. Calves of the 2nd group were during whole experiment fed with the milk replacers and the starter feed mixture. For the first 35 days they received liquid milk. Subsequently, they were habited on pelleted milk (1x liquid milk, 1x pelleted milk and starter feed mixture) up to weight 85 kg. The experimental period of both group started at initial body weight 85 kg in group barns, 10 calves each. All animal experiments and procedures were approved by the Ethics Committee of the Slovak University of Agriculture Animals were slaughtered after about 4 months of treatment in the experimental abattoir of Slovak University of Agriculture (SUA) in Nitra. At slaughter were carcass composition recorded. After 24 hours chilling, detailed dissection from the right - half carcass into meat cuts was carried out. Immediately, slices of loin and top round muscles were removed from right-half carcass for the proximate composition and physical technological parameters of veal. Weight and percentage of lean meat, separable fat and bones (technical, marrow, pelvis, scapula) from the hindquarter and forequarter of right-half carcass were determined. Meat cuts were separated according to 1st quality class meat including top round, sirloin, tenderloin, shortloin, shoulder; 2nd quality class meat including neck, fore - shank, brisket, rib, short plate, flank, hind – shank. Parameters associated with the mat quality (pH, electrical conductivity, drip loss and colour measurements) were evaluated 24 hours *post mortem*. Analyses of qualitative and physical technological parameters were performed using standard instruments in the laboratories of SUA in Nitra. For statistical evaluation of results were calculated basic variability and statistical characteristics using the Statistical Analysis System (SAS) version 9.3 (TS1M2) Enterprise Guide 5.1. (SAS INSTITUTE Inc., 2011).

Results and discussion

Experimental group (2nd) of calves fed with granulated milk replacer was lighter at the end of fattening ($P<0.05$) as well as at slaughter ($P<0.05$), as shown in Table 1. The carcass weight was higher in the first group of calves ($P>0.05$). Dietary effects on growth rate were revealed, while they may consist in different rumen development or rate of muscle deposition (Noon *et al.,* 1998). Diet slightly significant influenced dressing percentage ($P<0.05$) as well as proportion of kidney fat ($P<0.05$); higher results were determined in the calves of second group. Variations in dressing percentage may depend on the dry matter content of milk or solid feed when feeding calves with diet, including mix diets (Vieira *et al*., 2005). Xiccato *et al*. (2002) found +10 kg higher final weight in calves fed with the maize grain supplement compared to exclusively milk fed calves. Moran *et al*. (1988) found in calves fed with whole milk with carcass weight of 66.7 kg weight of kidney fat 1.26 kg.

Table 1. Average slaughter characteristics of Holstein male calves with different feeding system.

	Weight (kg)		*Sign.*	Percentage (%)		*Sign.*
	Group I	Group II		Group I	Group II

Table 2 describes weight of meat quality classes from right – half carcasses of calves with different feeding system. Higher proportion of the 1st choice meat as well as 2nd choice meat were determined in the calves fed with granulated milk, results were not significant (P>0.05). Feeding system had little effect on longissimus area (P<0.05). Our results in MLD area of the 1st group were similar to those of Titi *et al*. (2008).

Table 2. Meat quality grades from Holstein male calves in different feeding system.

	Weight (kg)		*Sign.*	Percentage (%)		*Sign.*
	Group I	Group II		Group I	Group II	
Right-half carcass	32.14±0.53	30.04±4.11	*ns*			
1st choice meat	22.44±0.63	21.16±2.85	*ns*	69.81±1.07	70.48±2.01	*ns*

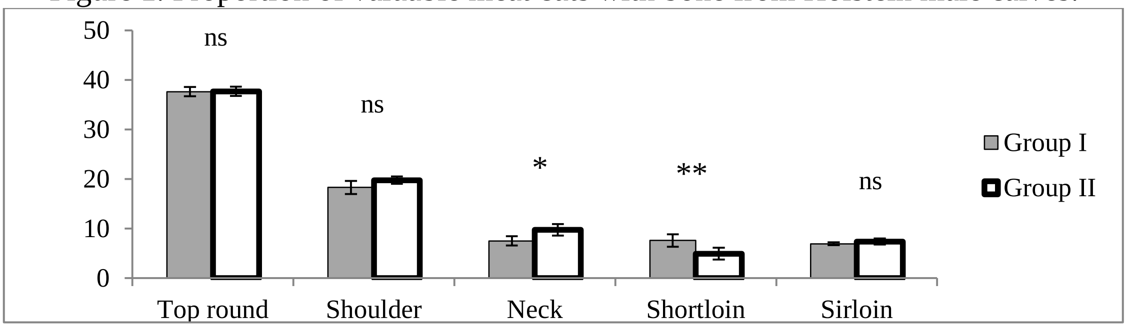
Values are mean ± standard deviation, * P<0.05, ns – not significant; [1] boneless

Figure 1. Proportion of valuable meat cuts with bone from Holstein male calves.



** P<0.01, * P<0.05, ns – not significant

The proportions of most valuable meat cuts from right – half carcass of calves fed with different diets are presented in Figure 1. Feeding with granulated milk influenced proportions of 1st choice meat including top round, shoulder and sirloin as well as neck from 2nd meat quality grade (P>0.05). Contrariwise, significant higher proportion of shortloin (P<0.05) was found in the 1st group. Our results are similar to those of Holló *et al*. (2013) in buffalo male calves (when calculated proportion of boneless meat cuts).

Minimal differences (P>0.05) in the proportion of the hindquarter and forequarter from the right – half carcass were recorded between groups (Table 3). Feeding system influenced proportion of meat from hindquarter, while a significantly higher proportion had calves of the 2nd group (P<0.05). Traditionally fed calves had higher proportion of bones (technical, marrow, pelvis and scapula) of both the quarters from right – half carcass (P<0.05). Calves of the 2nd group had higher proportion of meat (P<0.05), lower proportion of bones (P>0.05) and separable fat (P>0.05) from hindquarter of right – half carcass. According to Moran and Curie (1992) Holstein calves are often considered unsuitable for the meat production due to their poor conformation of the hindquarters and thus highly priced meat of carcasses with lower muscularity. In contrast with our findings, Moran and Currie (1992) reported weight of forequarter 14.27 kg and forequarter meat 7.62 kg.

Table 3. Individual tissues from quarters of right – half carcass of Holstein male calves.

Values are mean ± standard deviation, * P<0.05, ns – not significant, [1]boneless meat, FQ – forequarter, HQ – hindquarter, SPF – separable fat

The pH taken on the loin muscle at 24 hours post mortem (Table 4) showed slightly higher values in the 1st group (P<0.05). Meat from calves fed with milk replacers usually had higher content of fat and lower pH value (Ngapo and Gariépy, 2006). No significant differences were found in the pH values on *M. semimembranosus* (P>0.05). According to Florek *et al*. (2015) the ultimate pH value of veal (usually measured within range between 2 days and 12 days *post mortem*) ranged from 5.54 to 5.64, which indicate the proper glycolysis process post mortem. Titi *et al*. (2008) reported lower values of pH_{24} (5.61) in Holstein calves. Feeding system had no effect on electrical conductivity of both the muscles (P>0.05). The loin muscle from calves fed with granulated milk had higher drip loss than those from traditionally fed (P>0.05). No significant differences in shear force were determined in MLT (P>0.05). Lower results in shear force were described in Gottardo *et al*. (2002). Schaefer (2007) did not found effect of diet composition and nutritional management to sensory characteristics of Holstein beef.

Table 4. Parameters associated with the veal quality of Holstein male calves.

	MLT		*Sign.*	SM		*Sign.*
	Group I	Group II		Group I	Group II

Redness	4.37±1.36	1.20±2.41	*	5.28±0.54	3.9±3.83	*ns*
Yellowness	10.1±1.10	8.83±0.45	*ns*	10.69±0.89	10.36±1.88	*ns*

Values are mean ± standard deviation, * P<0.05, ns – not significant; SM - *M. semimembranosus*

Colour measurements of MLT (Table 4) designated light and pink meat. A higher L* value was measured in 2nd group (P>0.05). Significant differences in redness of loin were confirmed between two feeding groups (4.37 vs. 1.20). The rate of post mortem protein degradation is directly dependent on the ultimate value of pH. In addition, degradation contributes to the spread of scattering on the meat surface resulting to increase in colour measurements (Florek *et al*., 2015). In contrast with our findings Scheeder *et al*. (1999) reported L* value 44.1 and b* value 7.5 in MLT of calves fed with milk replacer. Opposite to our findings Titi *et al*. (2008) found in Holstein calves with slaughter weight 370.5 kg markedly darker (L* - 32.7) and slightly redder meat (a* - 5.0). In agreement with our findings, the study of Ngapo and Gariépy (2006) show that grain fed calves produce darker meat compare to exclusively milk fed calves, due to a higher content of haemoglobin. Calves in study of Scheeder *et al*. (1999) were fed with milk replacers or maize silage and concentrate feed mixture. They found markedly darker meat (L*:a*:b* 44,1: 12,3: 7,5) in the second group.

Table 5. Proximate composition of the loin muscle from Holstein male calves.

	Group I	Group II	*Sign.*
Moisture (%)	75.13±0.02	76.85±1.07	*
Protein (%)	22.38±0.49	22.06±0.56	*ns*
Intramuscular fat (%)	1.75±0.71	1.79±0.15	*ns*
EV (kJ.100g^{-1})	440.96±0.58	437.07±5.69	*ns*

Values are mean ± standard deviation, * P<0.05, ns – not significant

Chemical composition of MLT samples from Holstein male calves are described in Table 5. The results showed significant effect of the treatment on moisture content (P<0.05). It was determined that meat from 1st group of calves had slightly higher protein content (P>0.05). According to Xiccato *et al*. (2002) increasing in consumption of milk in diet resulted to higher fat percentage in carcasses. We found minimal differences in energy value as well as in intramuscular fat of monitored groups (P>0.05) (P>0.05). Holló *et al*. (2013) reported in buffalo suckling male calves content of protein 20.99% and fat content 0.63%.

Conclusion

Recently, several foreign papers describe the effect (especially in heifers) of so-called early weaning from liquid milk replacers and its replacement with granulated dairy feed mixture. Papers mentioned faster growth, increased intake of solid fee, greater rumen development, greater health and consequent higher utility of dairy cows. In our experiment we tested the liquid dairy mixture replacement with a granulated milk mixture for the meat performance of the Holstein calves. Although we found in the fattening indicators lower average daily gains of the experimental group (group II) in comparison to traditionally fed calves, variability of monitored indicators were lower. On the other hand, calves of the experimental group in the given weight category, had greater most of carcass values, which was also reflected in the larger body shapes of calves. In terms of meat quality indicators, the most important influence of the feeding system shown to be in lighter and pinker meat colour. However, mentioned results need to be verified in a greater extent and with a higher number of animals.

Abstract

In this paper we considered the possibilities for controlling or reducing the N losses and increasing N use efficiency in dairy cattle by using optimized feeding strategy and diet formulation. Ruminants have a low efficiency of N utilization compared with non-ruminants, whereas the N use efficiency in dairy cows is usually between 22 and 33%. The ruminal ammonia-N concentration between 6 and 18 mM is required to maximize microbial protein synthesis. Dietary strategies to reduce N losses should focus on an optimal supply of rumen degradable protein (RDP) and optimal efficiency of absorbed amino acid utilization for milk protein synthesis. Synchronization of the supply of rumen available protein and energy is an important factor for improving the utilization of dietary N. The optimal ratio of N to rumen fermentable OM is around 25 g/kg. A crude protein (CP) concentration in diets for lactating cows should be reduced to 15% DM to improve N efficiency and reduce environmental impact. Increased ratio of energy to protein improves N utilization and milk protein content as well as decreases milk urea N (MUN). Feeding adequate readily fermentable carbohydrates is critical for the efficient microbial capture of rumen available N. Improving the utilization of dietary protein is important for significant improvements in whole farm N balances, increasing the conversion of dietary N to animal products and providing opportunity for reducing environmental N losses.

Key words: *Dairy cows, Nutrition, Protein, Energy, Urea.*

Introduction

The low efficiency of dietary nitrogen utilization in ruminants is attributable primarily to the effects of the rumen microbes on nitrogen utilization. Dairy cows have specific requirements for amino acids that must be supplied either directly by the diet, or by rumen microbes flowing out of the rumen in the digesta. Feeding excess CP can result in unnecessary feeding expenses with no return in milk or milk protein yield. Approximately 75-85% of the excessive protein provided in rations are excreted, mostly in the urine. There is a direct relationship between the level of CP in dairy cattle rations and the amount of nitrogen excreted (Stojanović *et al*., 2004). The level of nitrogen excreted in the feces of animals is generally constant and cannot be significantly altered. In contrast, the level of nitrogen in the urine can be effectively controlled by balancing protein and energy needs of cows. Urea is the most variable component in urine, contributing from 50-90% of all N in urine. Dairy cows remove approximately 2.5-3.0% of the total amount of urea by produced milk.

Strategy to reduce N losses should focus on an optimal supply of rumen degradable protein (RDP) and optimal efficiency of absorbed AA utilization for milk protein synthesis (Stojanović *et al*., 2010). Rumen microbes need energy to be able to capture ammonia, and use it as an N source for growth. Carbohydrates fermented in rumen are the main source of energy required by microbes to utilize dietary and endogenous N, and increase the supply of AA to the small intestine (Stojanović *et al*., 2006). Synchronization of the supply of rumen available protein and energy is an important factor for improving the nitrogen use efficiency (NUE) from rumen degradable protein (RDP). Providing the high quantities of energy from readily fermentable carbohydrates in rumen, in synchrony with produced ammonia reducing the lag in energy supply as fibrous carbohydrates are fermented (Stojanović *et al*., 2014). Ruminants have significant capacity to recycle N absorbed from the digestive tract, and dietary manipulation should be aimed to provide the appropriate energy supply which corresponds with amount of ruminally available N.

Monitoring of blood or milk urea nitrogen (BUN, MUN) can be used for measuring protein and energy status in dairy cattle as these values are positively associated with rumen NH_3 concentrations. Blood urea nitrogen is highly correlated with ruminal ammonia, and MUN is highly correlated with BUN (r^2 = 0.72-0.98), and their values are indicators of the protein to energy ratio in the diet (Stojanović *et al*., 2007).

The aim of this paper was to show the main pathways of N metabolism and losses in dairy cattle, and to consider the possibilities for controlling or reducing the N losses and increasing N use efficiency by using optimized feeding strategy and diet formulation.

Efficiency of nitrogen utilization in dairy cattle

Ruminants have a low efficiency of nitrogen utilization compared with non-ruminants, with approximately 72% of N intake excreted in manure. Rumen metabolism is the most important factor contributing to the inefficient use of N in ruminants. Nitrogen losses in dairy cattle include: urinary excretion of urea synthesized from ammonia produced in the rumen; undigested microbial protein excreted in feces; microbial nucleic acids synthesized in the rumen and excreted mainly in urine; fecal and urinary excretion resulting from endogenous secretions; and urinary excretion related to maintenance and milk protein synthesis. The theoretical upper limit of nitrogen use efficiency (NUE) in a lactating cows is 0.40-0.45, but usually is well below this maximal value, between 0.22 and 0.33 (Dijkstra *et al*., 2013). Cows with higher DM intake and milk yield on diets contain a lower CP and higher non-fibre carbohydrates (NFC) have higher NUE.

The ruminal ammonia-N concentration between 6 and 18 mM is required to maximize microbial protein synthesis (Reynal and Broderick, 2005). However, benefits of supplying amino acids and peptides on rumen microbial protein synthesis and efficiency are significant. The efficiency of synthesis of microbial CP in the presence of AA and peptides, compared with NH_3 is about 20% higher when expressed per unit of fermented organic matter (OM), (Dijkstra *et al*., 2013).

The lowest loss of N (35 g/day) is at an efficiency of microbial CP synthesis of 25.2 g microbial N/kg rumen fermentable OM (Bach *et al*., 2005). Dietary rumen available N content should be 15 g/kg DM or 94 g CP/kg DM. Surplus of rumen degradable protein is excreted as urea-N in urine. Bacterial CP synthesis in rumen was estimated to be 130 g/kg TDN (NRC, 2001).

Ruminants have the ability for nitrogen recycling and by that to save the urea N from excretion and transfer it back to the gastrointestinal tract. This is provided by the urea transfer from the blood across the epithelial tissue or through the saliva, and is a significant source of N for rumen microorganisms. Depending on dietary CP concentration, urea recycling back to the gut can be from 19-96% of endogenous production, and of this, 35-55% may be used for microbial protein synthesis (Lapierre and Lobley, 2001). The recycling of N to the rumen and incorporation into microbial protein is especially significant for the efficient use of diets with low CP content. Holstein heifers capture approximately 43% of the N recycled back to the digestive tract when fed low CP diets compared to 6% when fed high CP diets (Marini and Van Amburgh, 2003).

Rumen microbial synthesis of nucleic acids (20-25% of rumen microbial N) leads to considerable losses of N particularly in urine, and there is no possibility to reduce losses of N related to nucleic acid synthesis in the rumen. The major end products of catabolism of

pyrimidines are β-amino acids and ammonia, as well as of catabolism of purine are allantoin, uric acid, xanthine and hypoxanthine.
The digestibility of microbial true protein and rumen undegradable protein (RUP) in the small intestine of cows is 80-85% (Stojanović and Grubić, 2008).
About the 65% of AA digested in the small intestine is recovered in the portal vein, whereas the losses are the endogenous protein synthesis (replacement of sloughed epithelial cells and synthesis of digestive enzymes) and oxidation of AA across the gut wall (Lapierre *et al*., 2006). The utilization efficiency of absorbed AA for milk protein synthesis is 64-68%. The utilization of available AA by the mammary gland is related to the supply of energy. Increased supply of metabolizable energy may reduce N losses in post-absorptive tissues.
Losses of N related to the maintenance are mostly unavoidable and include tissue maintenance requirements, skin secretions and scurf, and hair losses.

Strategies to increase nitrogen use efficiency in dairy cows

The most commonly used approaches to improve N utilization in dairy cows including reducing dietary CP content, increasing ruminal energy supply, synchronizing ruminal energy and protein supply, and balancing the supply of AA to the duodenum.
The catabolism of absorbed essential amino acids by the liver and other body tissues is largely determined by the extent to which they are absorbed in excess of requirement, which is largely determined by the rate of protein synthesis and secretion by the mammary gland (Reynolds and Kristensen, 2008). The key factor determining post-absorptive nitrogen use efficiency is the rate of milk protein secretion by the mammary gland relative to the rate of absorption of the individual AA required for milk protein synthesis.
The extent, to which ammonia is used to synthesize microbial protein in rumen, is largely dependent upon the availability of energy generated by the fermentation of carbohydrates. On average, 20 g of bacterial protein is synthesized per 100 g of OM fermented in the rumen. Bacterial protein synthesis may range from less than 400 g/day to about 1500 g/day, depending primarily on the digestibility of the diet.
With increase the supply of energy to rumen microbes while the RDP content does not change, less ammonia-N is formed and lost as urea-N in urine. The N use efficiency of a low energy and high protein diet can be improved from 0.20 to 0.24 when either supply of protein is reduced or supply of energy is increased, and can be improved to 0.28 with both (Rius *et al*. 2010).
The increase of dietary CP from 15.1 to 16.7% at the low and medium energy levels, significantly increase milk and milk protein yield, and there is no effect of increasing CP beyond 16.7% (Broderick *et al*. 2003). Milk and milk protein yield is also increased with ration energy increasing. Grings *et al*. (1991) found increase in milk yield with increasing dietary CP content from 13.8 to 17.5% but determined little benefit from increasing CP above 17.5%. Castillo *et al*. (2000) concluded that CP concentrations should be reduced to 15% DM to improve N efficiency and reduce environmental impact, and compared to diets containing 20% CP, this would reduce N excretion in the feces by 21% and N excretion in the urine by 66%. An increase in dietary CP from 13 to 18% DM led to a higher concentration of urea in milk from 7.0 to more than 15.0 mg/dL (Kebreab *et al*. 2002).
When low protein diets for lactating cows is used, to sustain high levels of production and milk protein yield, the rumen protected methionine and lysine should be used, because it has been shown for these essential AA to be the most limiting AA for milk production when dietary protein supply is low (Stojanović *et al*., 2010).
Increased ratio of energy to protein improves N utilization and milk protein content as well as decreases MUN. Feeding a concentrate based on ground shelled corn at the same time as high quality fresh pasture decreased the concentration of NH_3 in the rumen by 33% (Kolver *et al*.,

1998). Addition of a barley-sugar beet pulp based concentrate to cows (up to 6 kg) fed fresh pasture increases a microbial protein available for absorption and decreases MUN (from 50.4 to 38.9 mg/dL), (Sairanen *et al*., 2005). Cows consuming only pasture had a NUE of around 21.0% while supplemented grazing cows with carbohydrate feeds improved their NUE by storing in the milk 24.6% of the ingested N (Keim and Anrique, 2011).

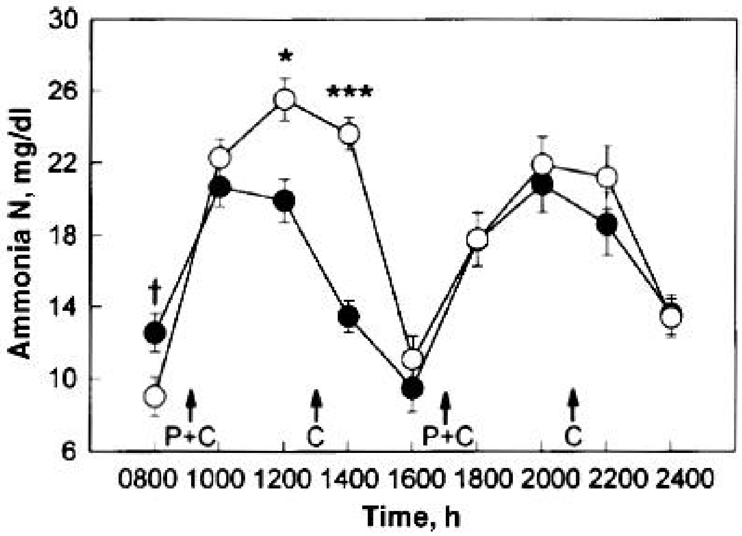

Figure 1. Diurnal pattern of ruminal ammonia N (mg/dL) of cows on pasture fed energy : protein synchronous (●) or asynchronous (○) diet (Kolver *et al*., 1998).

The relationship between milk protein content and dietary energy intake is much stronger than that with dietary protein intake. This is attributed to increased flows of microbial protein to the duodenum, but could also be explained by endocrine changes that affect the use of AA by the mammary gland (Griinari *et al*., 1997). Energy status affects insulin and the IGF (insulin like growth factor) system which have important roles in nutrient partitioning and milk protein synthesis.

Tannins as bioactive plant factors have high affinity towards proteins, and by forming the complexes reduce soluble protein fractions amount. The tannin-protein bonds are cleaved under the acidic conditions in the abomasum, and protein can further be digested in abomasum and small intestine. Lactating cows fed with silage containing different levels of condensed tannins from birdsfoot trefoil (*Lotus corniculatus*) or with added tannin extract at dosages of 15 and 30 g/kg DM had reduced milk urea nitrogen, ruminal ammonia and urinary N excretion (Davidović *et al*., 2018).

For MUN content, it is generally accepted that the range of 15.0-25.0 mg/dL is optimal in terms of protein and energy balance in rations for dairy cattle. In high producing dairy cows, BUN or MUN concentrations of less than about 15 mg/dL indicate a relative deficiency of dietary protein.

Urea nitrogen concentrations of greater than 19 to 20 mg/dL have been associated with reduced conception and pregnancy rates in dairy cows (Stojanović *et al.*, 2007). Urea has a significant impact on the percentage of pregnant cows after the first insemination procedure. The fertility is by 21.4% higher in the group of cows with a milk urea level <19.0 mg/dL, when compared to cows which milk contained >19.0 mg/dL of MUN (Butler *et al.*, 1996).

Conclusion

The nitrogen utilization efficiency in ruminants depends primarily of the effects of the rumen microbes on dietary CP utilization. In order to improve the efficiency of dietary CP utilization and minimize nitrogen excretion and environmental impacts, the most effective approach is to decrease concentration of protein in ration for dairy cattle. A CP concentration between 14 and 16% DM is probably adequate to meet the requirements of lactating dairy cows. Increasing ruminal energy supply, synchronizing ruminal available energy and protein supply, and balancing the supply of AA to the duodenum are also effective for increasing N use efficiency. With low protein diets for lactating cows, the rumen protected methionine and lysine should be used, as these essential AA are the most limiting for milk production. Reducing the soluble protein fractions in ration, lowers milk urea nitrogen, ruminal ammonia and urinary N excretion. The range of MUN between 15.0-25.0 mg/dL is optimal in terms of protein and energy balance in rations for dairy cattle.

Abstract

Soybean meal is the commonly used source of dietary protein in poultry feed. However, around 98% of soybean meal is produced from genetically modified plants. An alternative protein source might be lupines (*Lupinus* spp.). However, the available information is insufficient to develop the diets with blue lupines. The purpose of our study was to determine the effects of soybean meal replacement with different amounts of blue lupine in the diets of turkeys on the growth rate, carcass and meat quality. Three hundred and sixty cross BIG-6 turkeys were allotted to control and five experimental groups of turkeys. The control group of turkeys was fed with the diet containing soybean meal, whereas the trial groups were offered different amounts (from 20 to 30%) of lupines. Group 4 and 5 were additionally given probiotic mixture Bio Plus 2B and allzyme SSF. Soybean oil replacement from 20 to 30% lupine in the diet had no influence on the growth rate, dressing percentage, edible parts and abdominal fat content of turkeys. The study indicated that lupines in the diet of turkeys had a different effect on the meat quality of different genders. Lupines did not have any negative effect on the meat quality of female turkeys and 30% lupines even improved the protein value index of breast muscles. However, 20–30 and 25–30% lupines in male turkey diets lowered dry matter and protein contents in breast muscles. The results of the study showed that the negative effect on the male breast muscle quality might be avoided using Bio Plus 2B or allzyme SSF additives in the male diets containing 30% lupines.

Keywords: *Anatomic carcass dissection data, chemical indicator, growth rate, lupine, turkey.*

Introduction

Soybean meal is the commonly used source of dietary protein in animal and poultry feed formulations around the world. However, it is indicated that 98% of soybean meal or cake are produced from genetically modified plants (Sieradzki *et al.*, 2006). The diet containing exceptionally high protein content (up to 26–28%) is needed for growing heavy-type turkey poults. So, the necessity arises to search for the alternative protein sources in poultry feeds that could completely or partially replace soya components in poultry feed formulation (Nalle, 2009). An alternative protein source for soybeans might be lupines (*Lupinus* spp.). Lupines possess good agronomic characteristics and they have no antinutritive factors, such as trypsin-inhibitor (Olver, 1987). The protein from lupines has all indispensable amino acids and well-digestible (Sujak *et al.* (2006). However, the worldwide production of grain lupine seeds is low. Predictable, the areas with lupines will be increasing in Lithuania, whereas currently the production of sweet lupines in our country is low. One of the most popular species of lupines in our country is the narrow-leafed lupine. 'Bora' is a narrow-leafed alkaloid-free variety of blue lupines. Several studies can be found on the efficiency of lupines in the diets of different species of animals and birds but there is no unanimous agreement regarding the highest possible amount of blue lupines in the diets of heavy-type turkeys. The studies of Mierlita (2014), Zdunczyk et al. (2014) and Krawczyk et al. (2015) indicated that from 6 to 30 % lupine in the turkey diets had no influence on their body weight if compared with lupine-free diets. Mierlita (2014) concluded that substituting soybean protein meals with white lupine beans in turkey broilers at a rate from 20 to 30% had no adverse effects on the slaughter indices, however, the diet containing over 30% of lupines had a negative impact on carcass features. Zdunczyk *et al.* (2014) indicated that the slaughter value of turkeys was not affected by feeding them 6 to18% sweet yellow lupine meal in comparison with the diet containing soybean meal. The studies of effect of lupines on the chemical indicators of goslings and chicken's meat showed that 5-20% of lupines in the feed had no influence on the meat indicators and on the contents of tryptophan and oxyprolin (Morkunas *et al*., 1995; Morkunas, 2002).

Currently, the demand for organic fowl is increasing both in Europe and Lithuania. However, the available information is insufficient to develop the diets with blue lupines that have no negative influence on the qualitative and quantitative indicators of meat.

The purpose of our study was to determine the efficiency of different amounts of blue narrow lupine seed meal in the diets for hybrid cross BIG-6 turkeys, to analyse the effects of the lupine content on the growth rate of turkeys, anatomic carcass dissection data and chemical indicators of breast and thigh muscles, and to determine the contents of tryptophan and oxyprolin in above muscles.

Material and methods

The study was carried out in turkey farm in the district of Anyksciai, Lithuania. A total three hundred sixty cross BIG-6 turkeys were assigned to control group and five experimental groups of 30 one-day-old turkeys each. The diet of the control group turkeys contained soybean meal, which for the turkeys was replaced by respectively 20, 25 and 30% 'Bora' variety blue narrow-lupine in Trial group 1, Trial group 2 and Trial groups 3, 4 and 5. Besides, the diet of the turkeys in Trial Group 4 was supplemented with 200 g of probiotic mixture Bio Plus 2B per 1000 kg of feed at all age periods. The diet of the turkeys in Trial group 5 was supplemented with 200 g allzyme SSF per 1000 kg of feed. Starting from 13 week, there was no genetically modified soybean meal in the diets of turkeys in Groups 3, 4 and 5. For all the groups, the amounts of lysine, methionine and threonine were, respectively, 16, 10.5 and 10.4 g per kg feed at the age of 0–4 weeks, from 5 to 8 weeks it was 14, 9.0 and 9.0 g, , from 9 to 12 weeks 12.1, 6.5, 7.9 g and from 13 to 16 weeks – 9.0, 5.2 and 6.3 g. During experimental period, water and feed were provided *ad libitum.* All the birds were reared under the same conditions, in accordance with the law for animal welfare and handling, and a substaatutory act by the State Food and Veterinary Service of Lithuanian Republic regarding the confirmation of the order on the animals for experiments, research, storage, maintenance and operating requirements (State News, 2012). Birds of all groups were weighed at 4, 8, 12 and 16 weeks of age. At the age of 16 weeks, three males and three females of average weight were chosen from each group for control slaughtering. Prior to slaughter, the birds had not been fed for 12 hours. Carcasses were anatomically dissected according to the methodological recommendation of anatomic carcass dissection and organoleptic evaluation of poultry. The chemical composition of meat was analyzed by standard AOAC methods (1990). The contents of tryptophan and oxyprolin in meat were determined by the methods of Marina & Shut (1970) and Kolar (1990). All analytical studies were carried out at the Analytical Laboratory of the Animal Science Institute of Lithuanian University of Health Sciences.

Processing of the data was performed using software Statistica (Data Analysis Software System, Version 7.0; StatSoft, Inc., Tulsa, OK, USA). The statistical evaluation of the results was performed using descriptive statistics and Student's t test for independent samples. The probability level of $p < 0.05$ was considered to be statistically significant.

Results and discussion

The variety of lupines used in our study contained 1% bitter lupine seeds, 94.12% dry matter, 5.12% crude fat, crude protein 37.22%, crude fibre 13.32%, crude ash 3.09%. In our study, there was no significant difference between turkeys' weights at the age of 4, 8, 12 and 16 weeks in both control and treated groups. The results of our study are in agreement with those of Mierlita (2014), Zdunczyk *et al.* (2014), Krawczyk *et al.* (2015) who indicated that lupine in the diet of heavy-type turkey**s** had no adverse effect on their body weight. However, our results do not agree with the findings of Mikulski *et al.* (2014) who indicated that the use of blue lupine in the diet had resulted in significantly higher body weight of turkeys. The different amounts of blue lupines in the diets of turkeys had no effects on the dressing percentage (Table 1), except for the significant difference between the control and Group 4 male turkeys fed diets containing 30% lupines and probiotics (+3.95%; $p<0.05$).

Feeding chickens lupines or no-lupines resulted in no significant difference for the dressing percentage in the studies by Nalle (2009), Morkunas *et al.* (1995), Olver (1987), Bekric *et al.* (1990) and Orda *et al.* (2006). Similar findings were observed in the studies by Witak *et al.* (2006) on feeding duckling's 2.5–15% yellow lupine, Mierlita (2014) on feeding male turkeys 20–30% white lupine, Mikulski *et al.* (2014) on feeding male turkeys 6–18% blue lupine and Krawczyk *et al.* (2015) on feeding female turkeys 8–24% yellow lupine. Contrary findings, i. e. higher dressing percentage values when feeding lupines, were reported by Morkunas (2002) in his study with goslings and Mierlita (2014) in the trials with male turkeys.

In our study, there were no differences found for the internal edible parts in treatment turkeys of both genders if compared with the control group ($p>0.05$). This is in disagreement with the data of Orda *et al.* (2006) and Mierlita (2014) who reported a significantly higher amount of internal edible parts in chickens fed 5–20% yellow lupines and turkey poults fed 40% white lupines. There was no correlation determined between the content of abdominal fat and the composition of the feed offered to both trial and control groups of turkeys of both genders. This is in agreement with the findings of Witak *et al.* (2006), Suchy *et al.* (2010) and Orda *et al.* (2006). On the contrary, Mikulski *et al.* (2014) indicated that 18% blue lupine in the diet of male turkeys had resulted in higher content of abdominal fat. Krawczyk *et al.* (2015) have also found that the content of abdominal fat tended to increase when female turkeys were given 8–24% yellow lupine. However, Bekric *et al.* (1990) reported that 23% lupines in the diet of chickens had influenced lower abdominal fat percent. The dry matter content in the male breast muscles (Table 2) trial groups 1, 2, 3 was from 1.95 to 2.31% lower (p<0.05–p<0.025), in Group 4 tended to decrease (–1.58%; p=0.08) in Group 5 was statistically insignificantly lower (–1.30 %; p>0.05) than that of male turkeys in the control group. The protein content in male breast

muscles in trial (Groups 2 and 3 was from 1.86 to 2.13% lower (p<0.05–p<0.025), in Groups 1, 4 and 5 tended to decrease from –1.64 to –2.43% (p=0.06–p=0.08) in comparison with the control group. Our findings for the dry matter content are contrary to those by Morkunas (2002) who indicated that male chickens fed the diet containing 10–20% lupines had from 0.48 to 1.77% higher dry matter content in breast muscles. No other data have been found regarding the dry matter and protein content in the breast muscles of heavy-type turkeys fed lupines. In our study was found that diet supplementation with lupines had not affected the dry matter and protein content data in the female breast muscle, male and female thigh muscles (Table 3, 4, 5).

This is in agreement with the results of Olver (1987) in the study with chickens fed 40% white lupine regarding dry matter difference, Suchy *et al.* (2010) regarding protein content difference, Froidmont *et al.* (2004), who found no difference for the above indicators in thigh muscles and Sitko & Čermak (1998) who indicated no difference for the protein content in breast and thigh muscles. Moreover, no difference for the dry matter and protein content in the breast muscles were reported by Krawzcyk *et al.* (2015) in the study with female turkeys fed 8–24% yellow lupine and Mikulski *et al.* (2014) in the study with male turkeys fed 6–18% blue lupine.

We found that the ash content in the thigh muscles of male turkeys was from 0.05 to 0.07% (p<0.05–p<0.025) and from 0.02 to 0.06% (p>0.05) lower in, respectively, Groups 3 and 5 and Groups 1, 2 and 4 in comparison with the control group. No significant differences for the ash content were found in the breast muscles of male and female turkeys and in the thigh muscles of female turkeys. This is in agreement with the findings of Suchy *et al.* (2010). The ash content in the breast muscles was in agreement with the results of Krawczyk *et al.* (2015) in the trial with turkeys fed from 8 to 24% yellow lupine. The oxyprolin content in the breast muscles of female turkeys was from 3.52 to 12.66 mg% lower if compared with the control group and statistically significant difference was found when compared with Groups 1, 3 and 4 ($p<0.01$–$p<0.001$). The protein value index in female muscles (Groups 1–4) was from 0.58 to 1.40 units higher in comparison with the control group. The oxyprolin content in the thigh muscles of male turkeys (Groups 1–4) was from 0.15 to 13.26 mg% higher in comparison with the control group and the significance was determined when comparing with Group 3 ($p<0.001$) and if compared with Group 4, this indicator tended to increase (+9.68 mg%, $p=0.09$).The protein value index in male thigh muscles was from 0.16 to 0.73 units lower in comparison with the control group. The differences of the results for the oxyprolin content in different male and female muscles are in agreement with the conclusion by Nalle (2009) that the gender of the bird might influence different meat quality indicators.

On the contrary, our data on the oxyprolin content partly in female breast and male thigh muscles contradicts the findings of Barroeta (2007) who noticed that the composition of the feed has no influence on the amino acid content in poultry meat and also do not agree the results of Leikus *et al.* (2004), Leikus (2006) and Juodka *et al.* (2016) who indicated that the use of lupine or peas in the feed had no effect on the oxyprolin content in meat.

Conclusion

It can be concluded that soybean oil meal replacement with lupine content from 20 to 30% in the diets of turkeys had no influence on the growth rate, dressing percentage, edible parts and abdominal fat content, except for the significantly lower dressing percentage in male turkeys fed 30% lupine and probiotic supplement if compared with a lupine free diet. The study indicated that lupines in the diet of turkeys had a different effect on the meat quality of different genders. Lupines did not have any negative effect on the meat quality of female turkeys and 30% lupines even improved the protein value index of breast muscles. However, 20–30 and 25–30% lupines in male turkey diets lowered dry matter and protein contents in breast muscles but had no negative influence on the main quality indicators in thigh muscles. The results of the study showed that the negative effect on the male breast muscle quality might be avoided using BioPlus2B or allzyme SSF additives in the male diets containing 30 % lupines.

Abstract

By establishing reproductive-production characteristics of broiler parent hybrids Cobb 500 the research has been conducted on one parent flock during the period of 38 weeks of production. During the research, special attention was given to breeding eggs incubation and diurnal chicken production. The main goal of this paperwork was establishing the impact of broiler parents' age on chicken effective incubation. During the production cycle in 3 periods (AP_{23}, AP_{31}, AP_{42}) the following was observed: the breeding egg mass on deposition, the breeding egg mass on shuffling, diurnal chicken mass, length of diurnal chickens, and chicken to egg ration. According to the tested periods, broilers' parent in the largest number of cases had the best reproduction-production values during the middle of production cycle (AP_{31}), in relation to the first and third testing period (AP_{23}, AP_{42}). Broiler parents' age influenced the incubation values of the eggs and one-day chicks. The average mass of fresh layed eggs was the biggest in the tested period (AP_{31}) - 69.32 g, while the biggest mass of the eggs on transshipment was in the third tested period (AP_{42}) -60.44 g. The incubational values of one-day chicks during the incubation were increased along with the broilers parents' age which had the consequence that mass and weight of chick were the biggest in 3rd tested period (AP_{42}) where average mass was 42.41 grams, and length 16.80 cm. Chick share had its specific variations according to other characteristics. The biggest average share of the chick in the egg mass was in the 23rd week, or in the first testing period and it was 69.91%.

The differences in the examined traits were considered significant at levels *P<0.05; **P<0.01.

The differences in the examined traits were considered significant at levels *P<0.05; **P<0.01.

Keywords: *age, parent flock, Cobb 500, incubation properties.*

Introduction

Production of one-day chickens as a final product includes two production cycles which are interconnected and conditioned by each other (and show some interaction), these are the breeding of the parent flock (the production of eggs for the plantation) and the artificial laying of chickens, that is, the incubation of breeding eggs. Production of one-day broiler chickens consists of several technological phases, "from eggs to chickens": breeding of the breeding flock of a heavy type of chicken, quality features eggs for plantations, the influence of genetic and paragenetic factors on their quality, the collection of eggs on the farm, selection and transport of breeding eggs from the farm to the incubator station, reception, storage (guarding) and preparation of eggs for incubation, investment of eggs in the incubator and general rules for artificial chick laying, egg process in the dressing room (up to 18 days of incubation), transferring eggs from the hens to the breeder, the process with eggs in the derivative (from day 18 to day 21) and laying (performing) chickens, extracting, grading, packing and dispatching one-day broiler chicks Stanišić (2012). The main goal of production is to find

optimal solutions in order to produce as high quality breeding eggs as each parent's flock, and therefore the maximum number of quality vital day-old chicks.
That the age of broiler parents affects the mass of eggs, that is, one-day chickens, the percentage of chickens in the weight of eggs, as well as the further development of broiler chickens, have been determined Shanawany (1987), Wilson (1991), Vieira and Moran (1998), Dalanezi *et al.* (2004), Vieira *et al.* (2005). The authors, among other things, conclude that with the age of broiler parents during the production cycle, as a rule, every week the mass of eggs increases.
Pinchasov (1991) states that the age of the laying hens has a lower effect on the weight of the chickens, that is, that the egg mass significantly has a greater effect on the weight of one-day chickens. The weight of the eggs affects the weight of the chickens and the percentage of chickens in the egg mass, according to Miclea and Zahan (2006), at the parent flock of the Ross SL 2000 hybrid grown from 35 to 49 weeks of age. Of the light eggs (average weight 54.59 g), chickens weighed 38.11 g, medium sized (58,89 g), chickens 40.74 g of heavy eggs (63.10 g) were chickens of average weight 43.18 g. Loss of embryonic mortality was higher in light (7.83%) and in heavy eggs (7.90%), compared to eggs of medium weight (6,67%).
Similar findings were obtained Traldi *et al.* (2011) and Wilson (1991), with the relative share of the chick mass in the egg mass ranged between 67% and 70%, or between 62% and 76%. Although Traldi *et al.* (2011) obtained in two experiments a similarly similar percentage of chickens in the mass of eggs in broiler hybrids Ross aged 29 and 55 weeks.
Abudabos (2010) found that Ross 308 and Cobb 500 hybrid parents found that with both the age of the flock both hybrids increase the mass of eggs and, therefore, the weight of one-day chickens. In the Cobb hybrid parent number of 26 weeks old, the weight of the eggs was 58,2 g, chickens 41.3g (percentage of chickens in the weight of eggs -71.00%), and in the age of 44 weeks eggs 75.8 g of chickens 51.6 g (71.50%), in the parents of hybrid Ross aged 32 weeks the average weight of eggs was 67.4 g, chickens 49.3 g (73.00%), and at the age of 36 weeks, the weight of eggs was 66,4 g and the weight of chickens was 48.3 g (73.10%).
Enting *et al.* (2007) examined the influence of the age of broiler parent hybrids Cobb 500 and the composition concentrates the concentrate on the incubation characteristics of the eggs for the plantations or broiler chickens. In the control group (fed normal-standard mixture) of broiler parents, the average weight of eggs at the age of 29 weeks was 55.4 g (day-old chickens – 35.9 g), at the age of 41 weeks, 67.0 g (41.8 g) and at the end of the production cycle (60th week of age), the weight of eggs on average was 71.4 g, and day-old chickens were 45.1 g. The authors conclude that with the age of broiler parents the weight of eggs and the weight of one-day chickens is increasing, while the percentage of chickens in eggs was the highest at the age of flocks of 29 weeks, 64.80%, then 60 weeks (63.16%), and the smallest in the 41st week (62.39%).
The main objective of this work and day-old chickens and to determine the impact of the age of the parent flock on the mentioned group of incubation properties through the three phases of the production cycle of breeding parent brooders of the Cobb 500 hybrid, or different ages of broiler parents (AP_{23}, AP_{31}, AP_{42}).

Material and Methods

The experimental part of the research was carried out on the poultry farm, i.e. the incubator station of the meat industry "Akova Group", Visoko, Bosnia and Herzegovina.
The initial experimental material was served by a flock of broiler parents of the Cobb 500 hybrid, grown on the parent farm from the 20th to the 60th week of age.
The monitoring of reproductive and production characteristics of broiler parents was carried out at the parent farm, and the determination of the efficiency of chick incubation in an incubator station within the said poultry farm.

An old 20-week-old parent's cattery from a nursery-growing facility was relocated to a breeding broiler facility. 28 128 pieces of laying hens and 3 380 pieces of roosters were brought into the breeding facility of broiler parents. 27 492 and laying hens 3 276 chicks were transferred to the production. Parental breeding began with the production of eggs at the end of the 22nd week of age, but eggs were used for incubation at the beginning of the 23rd week of age until the 60th week of age. During the cultivation (production of eggs) of the examined parent flock, the technology proposed by the hybrid selector Cobb 500 (www.cobb-vantress.com) was used. Nutrition, power, ventilation and lighting are automatically regulated.
In order to determine the influence of age of numerical parents on the efficiency of chick incubation during the production cycle, eggs were incubated three times, selected by the random sample method. In each week (AP_{23}, AP_{31}, AP_{42}), by random sample method, 200 eggs were taken, i.e. a total of 600 eggs. All eggs are stored in a storage room that is air conditioned with the possibility of humidifying the air with an air humidifier in the form of a water mist.
In each examined egg period, the eggs were individually measured before being incubated (incubator) and on the 18th day of incubation (before transferring to the derivative), while the chickens were measured directly at the bed (21st day of incubation). During the incubation, egg-shaping processes were performed to have an approximate insight into the state of fertilization of eggs.

Reproductive - production characteristics for which individual data are made are:

1. Weight of breeding eggs on investment, (g)
2. Weight of breeding eggs on postponement (Day 18), (g)
3. Mass of day-old chickens, (g)
4. Length of day-old chickens, (cm)
5. Relative share of chickens in egg mass (chick mass / egg mass) x100

Basic data processing was done in SPSS v. 22 package software. For the indicators that are processed individually, the following are calculated: mean ($\bar{x}$), standard error of the mean (S $\bar{x}$), standard deviation (S), and variation coefficient (C.V.)
Testing the significance of the difference between the incubation values tested was performed with a formula with the same number of repetitions Hadživuković (1973).

Results and Discussion

According to the plan and program of this study in the incubator station, the reproductive properties, that is, the incubation values of breeding eggs during the breeding of broiler rodents of hybrid Cobb 500 were investigated.
Table 1 gives the average values and variables for the investment egg mass, the weight of eggs on the shift of day 18, the weight and length of day-old chickens, and the share of chickens in the egg mass for the three examined periods.

Table 1. Average values and variability for the properties of eggs and day-old chicks for all three load periods, depending on the age of numerical parents.

Age of parents (AP)	Properties	$(\bar{x})$	S	$S(\bar{x})$	C.V. (%)
AP_{23}	The weight of eggs on investment	55.30	2.06	0.14	3.72
	The weight of eggs on postponement	49.47	2.37	0.17	4.79
	Mass of day-old chicks	38.46	2.46	0.17	6.39
	Length of day-old chicks	16.14	0.64	0.04	3.96
	Chicken share in egg mass	69.91	5.60	0.39	8.01
AP_{31}	The weight of eggs on investment	69.32	4.37	0.31	6.30
	The weight of eggs on postponement	58.52	4.11	0.29	7.02
	Mass of day-old chicks	42.05	2.56	0.18	6.08
	Length of day-old chicks	16.32	0.67	0.05	4.10
	Chicken share in egg mass	60.89	5.42	0.38	8.90
AP_{42}	The weight of eggs on investment	68.33	3.51	0.25	5.13
	The weight of eggs on postponement	60.44	3.10	0.22	5.12
	Mass of day-old chicks	42.41	2.87	0.20	6.76
	Length of day-old chicks	16.80	0.54	0.04	3.22
	Chicken share in egg mass	61.10	6.03	0.43	9.86

The average weight of all eggs originating from the young flock (AP_{23}) was 55.30 g, then increased with age (AP_{31}) to 69.32 g, and then fell again to 68.33 g at 42 weeks of age. Unlike the average weight of eggs on the investment, the egg-laying eggs (day 18) with the age of the parents increased throughout all three examined periods. Analogously to the mass of eggs, the weight of one-day chickens increased with the age of broiler parents. For AP_{23}, the average weight of day-old chickens was 38.46 g, for AP_{31} 42.05 g and for AP_{42} 42.41 g, which is in line with the studies carried out by Yildrim (2005), Christensen *et al.* (2002). The highest relative share of chickens in eggs was in the first study period (AP_{23} – 69.91 %), slightly lower in the third study period (AP_{42} – 61.10 %), while the smallest was in the middle of the production cycle (AP_{31} 60.89 %). To similar results, and the same contations, relative to the relative share of chickens in the egg mass, came Enting *et al.* (2007). In addition, the data in Table 1 shows that deviations from the average values of individual egg and chicken characteristics were small, i.e. the coefficient of variation ranged from 3.22% (length of day-old chickens – AP_{42}) to 9.86% (share of chickens in egg mass – AP_{42}).

Table 2 shows the significance of the calculated differences between the average values for the investment egg weight, the weight of the eggs on the shift of day 18, the weight and length of day-old chickens, and the share of chickens in the egg mass for the three examined periods.

Table 2. Significance of differences in the reproductive characteristics of eggs and day-old chicks, depending on the age of the parent (AP).

Properties	Age of parents. weeks (AP)	$(\bar{x})$	d	Significance
The weight of eggs on the investment (g)	$AP_{23} – AP_{31}$ $AP_{23} – AP_{42}$ $AP_{31} – AP_{42}$	55.30 – 69.32 55.30 – 68.33 68.33 – 69.32	-14.02 -13.03 0.99	** ** ns
The weight of eggs on postponement (g)	$AP_{23} – AP_{31}$ $AP_{23} – AP_{42}$ $AP_{31} – AP_{42}$	49.47 – 58.52 49.47 – 60.44 58.52 – 60.44	-9.05 -10.97 -1.92	** ** *
Mass of day-old chicks (g)	$AP_{23} – AP_{31}$ $AP_{23} – AP_{42}$ $AP_{31} – AP_{42}$	38.46 – 42.05 38.46 – 42.41 42.05 – 42.41	-3.59 -3.95 -0.36	** ** ns
Length of day-old chicks (cm)	$AP_{23} – AP_{31}$ $AP_{23} – AP_{42}$ $AP_{31} – AP_{42}$	16.14 – 16.32 16.14 – 16.80 16.32 – 16.80	-0.18 -0.59 -0.41	ns ns ns
Chicken share in egg mass (%)	$AP_{23} – AP_{31}$ $AP_{23} – AP_{42}$ $AP_{31} – AP_{42}$	69.91 – 60.89 69.91 – 61.10 60.89 – 61.10	9.02 8.81 -0.21	** ** ns

**P<0,01; *P<0,05; ^{ns}P>0,05

From Table 2 we can see that for the mass of eggs, significant meanings of average values were reported between AP_{23} and AP_{42}, and there were no statistical significances between AP_{31} and AP_{42}. The weight of eggs on the transfer of statistical significance was in the ratio between all three examined periods. When it comes to the mass of day-old chicks and the share of chickens in the egg mass, the same results were achieved as for the egg-weight of the investment, while for the length of one-day chickens statistical significance did not occur between any examined period. Similar results have been obtained by Enting *et al.* (2007), Abudabos (2010).

Conclusions

Based on the results of the study of the influence of the age of numerical parents (AP) on the incubation values of day-old chicks conducted on the Cobb 500 heavy line hybrid flock, the following conclusions can be drawn:

- Indicators of descriptive statistics for the characteristics of eggs and day-old chicks for all three load periods showed that the average weight of breeding eggs on investment was the highest in the second study period (AP_{31}) of 69.32 g while the smallest was in the first study period (AP_{23}) 55.30 g.
- The average weight of breeding eggs on postponement was the highest in the third study period (AP_{42}) of 60.44 g, and the smallest in the 23 weeks age (49.47 g).
- The highest average weight of day-old chicks was 42.41 g (AP_{42}), and the smallest 38.46 g (AP_{23}).

- The length of day-old chicks ranged from 16.14 cm in the 23rd to 16.80 cm at the 42nd week of the parents.
- The average share of chickens in eggs ranged opposite to other characteristics, so it was the highest in the 23rd week (69.91%) while the smallest was in the 31st week old age.
- The average value of egg masses on investment of significance was reported between AP_{23} and AP_{31}, as well as between AP_{23} and AP_{42} at $P<0.01$, while there were no statistical significances between AP_{31} and AP_{42} ($P> 0.05$).
- In the case of weight of eggs on the spread of statistical significance, they all occurred between all three examined periods at the level of $P<0.01$ and $P<0.05$.
- With the average values of the weight of one-day chicks and the share of chickens in the weight of eggs, the significance ranged at the same levels as the average values of egg weight on the investment.
- For the value of the length of day-old chickens of statistical significance, there was not a single study period ($P>0.05$).

From all of the above, it can be said that the age of the brooding parents of the Cobb 500 hybrid on farm conditions influenced in a certain way all the traits, except for the length of one-day chickens.

Abstract

Yogurt is very popular fermented dairy product, already considered to be healthy food. Due to low calorie value, low fat yogurts have gained popularity in recent years. Quality, rheological and sensory characteristics of yogurt depend on many factors including milk type and its fat content, the microflora used and the applied technology. In Serbia, low fat yogurt is consumed as stirred and Greek style yogurt. Many consumers experienced these products as sour, insufficiently viscous or grainy. Therefore this work aimed to determine composition, sensory quality and some rheological characteristics of low fat yogurts with milk fat (MF) in the range 0-2 % that could be found on Serbian market. As expected, due to specific production process, the highest levels of total solids (13.54% and 15.69%) and proteins (8.01% and 7.90%) were detected in Greek-style yogurts with 0% and 2% MF. Significantly higher ($p<0.05$) values of viscosity were recorded in Greek style yoghurts. Among stirred yogurt samples, the highest viscosity was determined in yogurts with 0.9% MF. The highest syneresis (44.15%) and the lowest viscosity were determined in samples with 1% MF. Greek-style yogurts with 0% and 2% MF had the lowest sensory ratings due to grainy consistency (as a result of high protein content) and higher acidity levels (1.38% and 1.32% l.a., respectively). According to all parameters of sensory quality, the best rated was yogurt with 0.9% MF.

Keywords: *Low fat yogurt, Viscosity, Synresis, Sensory characteristics.*

Introduction

Recent health trends favor the consumption of nonfat and low fat foods, especially dairy products. In yogurt, the reduction of fat has negative effects on yogurt characteristics such as lack flavor, week structure and syneresis (Kahkonen and Tuorila, 1999; Lucey and Singh, 1997), which led to lowering the consumer's acceptability of these products. During the past two decades, many attempts have been made to produce non fat and low fat yogurts which are similar in quality to full fat yogurt. Commonly used approaches for improving quality of low fat yoghurt are changing the formulation of the yoghurts (addition of fat replacers, thickening agents, milk fortifiers, etc.), using exopolysaccharide producing starter cultures, introducing modifications in the manufacturing process, addition of flavours or a combination of these methods (Prasanna et al., 2013; Torres et al., 2011; Trejo et al., 2014). Since all of the above increases to the cost of the production, many dairies produce stirred non fat and low fat yogurt from standardized milk by same technology used for full fat yogurt. On the other hand, Greek yogurt is characterized with high content of total solids. On the Serbian market it could be found as low fat Greek yogurt and as yogurt with high fat content in type of Greek yogurt. Methods for achieving required total solids content are different according to the type of Greek yogurt, and equipment and technology of the producers. All this indicates different quality of low fat yogurts consumed in Serbia. Thus the aim of this work was to investigate physico-chemical, some rheological and sensory characteristics of low fat yogurt available on Serbian market.

Material and method

Twelve samples of non fat and low fat yogurts of different companies that could be found on Serbian market were collected. Samples were transported in refrigerated vans and stored in refrigerators at 4^0 C, once at our laboratory. Basic analysis of physico-chemical composition of yogurt samples were done with the following methods: total solids (Carić et al., 2000), proteins (IDF 20B:1993), fat in yogurt (Carić et al., 2000), titrable acidity (IDF 105:1991), pH value with pH meter (Consort C931). Each analysis was done in triplicate. Syneresis was determined according to the Ramirez-Santiago et al. (2010): 40 g of yogurt is weighed in a cuvette and centrifuged at 220 g for 10 min at 4^0 C. After centrifugation, the separated whey was measured and shown as percent of 100 g of the sample. For these tests, Laboratory Centrifuges (Ependorf, USA) was used. These analyses were done in duplicate.

Measurements of viscosity were done with Visco Basic+R Viscometer (Fungilab, Spain) at constant speed of spindle rotation. At the beginning, during the first 30 seconds, the speed is 100 rpm and then adjusted to 20 rpm. Readings were performed every 30 seconds (a total of 6 readings). For each yogurt test was performed twice and the average viscosity was calculated.

The overall sensory quality was determined by point rating scale method (Radovanović and Popov-Raljić, 2001) by trained judges.

The effect of milk fat content on yogurt characteristics was analyzed using Statistica 6.0 software (Stat Soft. Inc., Tulsa, USA), using analysis of variance (ANOVA). Mean comparisons of the parameters were performed by t-test, with the level of significance at 0.05.

Results and discussion

Yogurt samples used in this study were produced from cow milk with different milk fat (MF) content in different geographical regions. Besides MF content, stirred and Greek-style yogurts are produced by different technological processes. Furthermore, each dairy plant has specific production process parameters regarding heat treatment, starter culture, fermentation, cooling and storage of yogurt. Therefore, differences in composition, sensory quality and some rheological characteristics of low fat yogurts are expected.

Physico-chemical characteristics of commercial yogurt samples with different milk fat content are shown in Table 1.

Table 1. Physico-chemical characteristics of Greek and stirred yogurts

Parameter Declared fat content (%)	TS (%)	MF (%)	TSNF (%)	Proteins (%)	Acidity (% l.a.)	pH

* TS – total solids, MF – milk fat, TSNF – total solids non fat

Different superscripts within the same column indicate that the means differ significantly ($p<0{,}05$).

Greek yogurts are characterized by high total solids and protein content which can be achieved by draining, centrifugal separation, ultrafiltration or addition of milk-protein based products. Therefore, as expected, relatively high TS contents were observed. Furthermore, lack of fat in fat-free Greek yogurt influenced significantly lower total solids content comparing to Greek yogurt with 2% MF ($p<0,05$). Although both yogurts had similar protein content, TSNF were higher in 2% Greek yogurt, probably due to higher lactose content. Acidity is a consequence of lactic acidification obtained at the end of incubation and post-acidification during storage. Stabilizers added in Greek yogurt production also have great influence on yogurt acidity. Differences in acidity of examined Greek yogurts could be a consequence of the type of used stabilizer, since yogurts with pectin or guar gum used as stabilizers show higher acidities than those containing xanthan or κ-carrageenan (Soukoulis et al., 2007). Comparing to stirred, Greek yogurts had much higher acidity (1,32 and 1,38% l.a.), which is also higher than the acidity of low fat Greek yogurts investigated by Serafeimidou et al. (2012).

Among stirred yogurts significantly lower protein contents were observed in yogurts with 0,9 and 2% MF ($p<0,05$). Higher protein levels indicate higher buffer capacity, so lower pH in yogurts with 0,9% MF (2,75% proteins) was expected. However, the highest pH was in samples with 2% MF and only 2,93% proteins. Since all yogurts were obtained from the market, possible explanation would be that these samples had shorter storage period.

Syneresis is separation of the liquid phase from the gel, and depends many factors such as: heat treatment of milk, total solids content, stabilizers used, rate and temperature of acidification, type of starter culture, acidity that occures as a result of the action of lactic acid bacteria, etc. Expulsion of whey (syneresis) of low fat yogurts is presented in Figure 1.

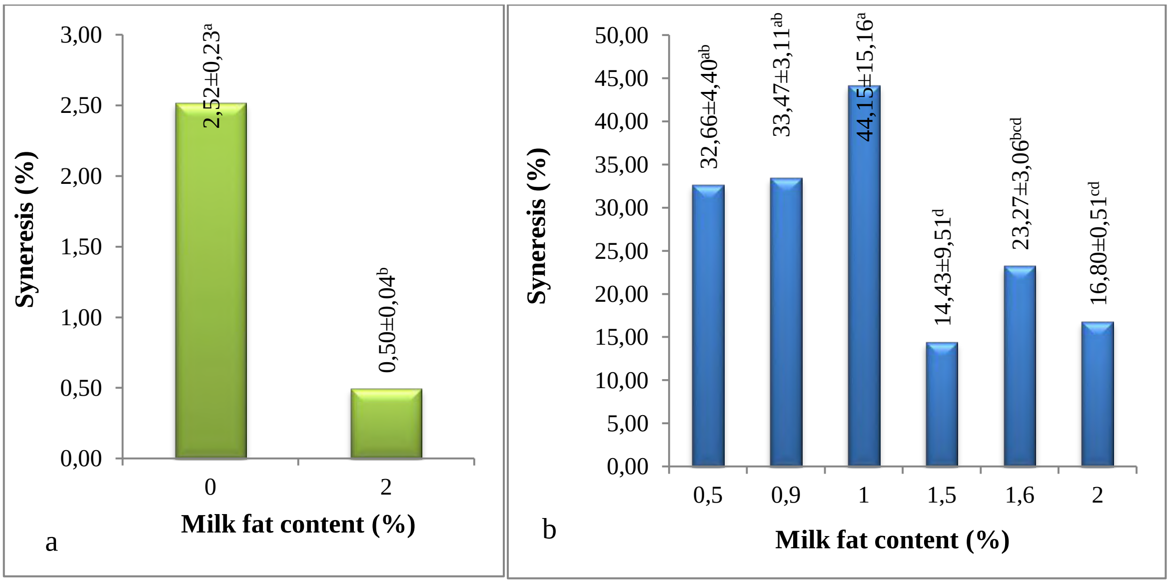

Figure 1. Syneresis of low fat yogurts (a – Greek yogurts, b – stirred yogurts)

*Different superscripts indicate that the means differ significantly ($p<0,05$).

Reduction of syneresis in yogurt could be achieved by the addition of casein-based ingredients (Guzmán-González et al., 2000) or whey protein-based products (Vučić et al., 2011). Greek yogurts had significantly higher protein content comparing to stirred yogurts, which could partially be due to addition of proteins, but they did not differ in protein content among each other. Therefore, approximately five times higher syneresis in non fat yogurt could be attributed to lower pH values. According to Harwalkar and Kalab (1986) lower pH values increase positive charge inside casein micelles and consequently intermolecular repulsion. As a result, pores in protein matrix are larger and therefore more intense whey separation occurs. Lowest expulsion of whey among stirred yogurts was observed in samples with 1,5% MF, while highest syneresis showed yogurts with 1% MF. However, those yogurts did not differ significantly regarding protein content and pH. It could be assumed that starter cultures that produce exopolysaccharides (EPS+ strains) were used in the production of yogurt with 1,5% MF, since EPS are characterized by a great water holding capacity which results in a reduced syneresis of yogurt.

Viscosity of yogurt is highly affected by milk composition, addition of proteins, heat treatment and type of starter culture. Hence, differences regarding viscosity between yogurts used in this investigation were expected. As previously mentioned Greek yogurts had similar protein content. But as a result of a higher fat content significantly higher viscosity ($p<0,05$) is observed in yogurt with 2% MF (Figure 2.a) Higher milk fat content leads to an increase in the viscosity of yoghurt, which has been confirmed by De Lorenzi et al. (1995).

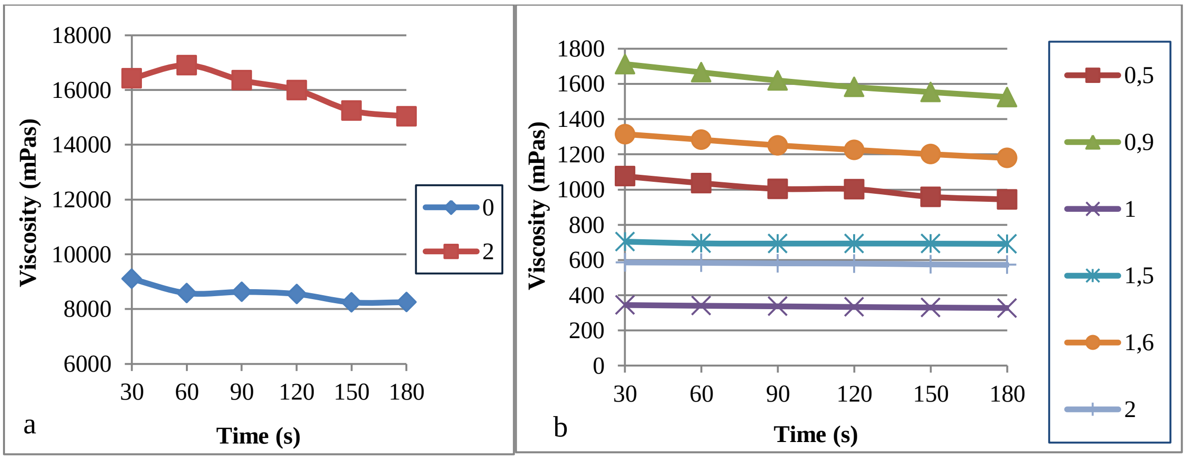

Figure 2. Viscosity of low fat yogurts (a – Greek; b – stirred)
* Numbers in Legend indicate declared fat content

Under the influence of the shear force, the viscosity decreases over time, and significantly lower viscosity is observed at the end of the measurement in yogurt with 2% MF. On the other hand, no significant change in viscosity was detected in yogurt with 0% MF which indicates the use of stabilizers in its production.

In stirred yogurt, breaking of gel structure under the influence of the shear force is less pronounced due to post-incubation operations (stirring, cooling and packaging) in which the structure of the gel has already been broken (Afonso and Maia, 1999). That is probably why viscosity hasn't significantly changed during measurement in all stirred yogurts, except in yogurt with 2% MF. Unexpectedly, the highest viscosity was observed in yogurt with 0,9% MF (Figure 2.b), although it had the lowest protein and TSNF contents. However, this yogurt also had the lowest pH, so it could be assumed that it had longer storage period. During storage, the protein matrix structure is rearranged, and the number of protein bonds within matrix increases leading to higher viscosity. Viscosity of yogurt with 0,9% MF was significantly higher comparing to yogurts with 1%, 1,5% and 2% MF ($p<0,05$). The lowest viscosity had yogurt with 1% MF which along with highest syneresis indicates week structure of protein matrix.

Acceptance of the product by consumers is mainly based on its sensory characteristics. The average score for each sensory attribute and the overall preference of the samples are shown in Figure 3. (a, b). Greek yogurts had lower sensory quality than stirred yogurts. Due to grainy consistency, acid and poor taste Greek yogurts had moderately low pondered mean values

(4,07 and 3,73, respectively). No significant differences were found in sensory quality of Greek yogurts regarding all parameters.

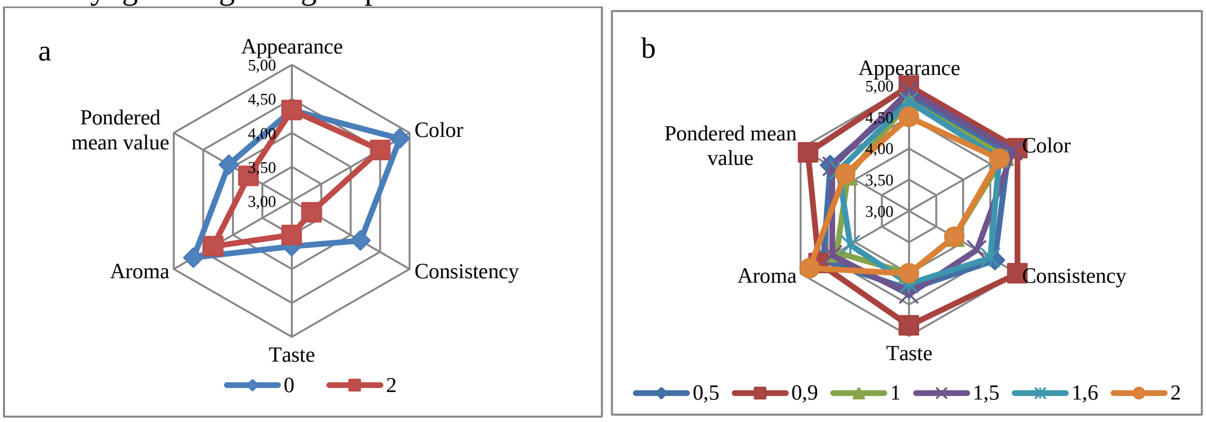

Figure 3. Sensory evaluation of low fat yogurt (a – Greek; b – stirred)
* Numbers in Legend indicate declared fat content

The sensory profile of all investigated stirred yogurts did not show any significant differences in the appearance, color, consistency, taste and aroma attributes. Scores obtained for the consistency were consistent with the results of viscosity measurement. Therefore yogurt with 0,9% MF had the highest consistency score. Also, this yogurt was evaluated as the best among investigated yogurts regarding all other sensory attributes except aroma. Consequently, the highest pondered mean value (4,86) was established in yogurt with 0,9% MF.

Conclusion

One way of utilization of skim milk in the production of fermented beverages is the production of low fat and non fat yogurt. Reduced energy value, slightly worse sensory characteristics, especially taste and consistency of these products require changes in the technological production process.

Investigations showed that two varieties of low fat yogurts (Greek and stirred) are present on Serbian market. Better rheological characteristics (significantly higher viscosity and very low syneresis – 0,5%) had Greek yogurt with 2% MF. Stirred yogurt with 0,9% MF had the highest sensory scores and therefore it was evaluated as the most acceptable.

Abstract

The aim of the study was to evaluate relationships between somatic cell count (SCC) and selected qualitative parameters of sheep milk (contents of fat (F), total protein (TP), casein (Cas) and lactose (L), pH, titratable acidity (TA) and clotting time (CT)). Determination of daily milk yield (DMY) and effect of the stage of lactation (SL) on selected parameters were also an integral part of the study. The study was carried out under operating conditions at a specialized sheep organic farm. Eighteen ewes of Lacaune breed were involved in the experiment. The SCCs insignificantly grew as lactation advanced, nevertheless, both mean counts (from 88 to 130 x 10^3/mL) and their counts in individual samples (from 36 to 420 x 10^3/mL) were relatively low during lactation. The SL also had no significant effect on pH and TA. On the other hand, the SL had a significant effect on all other monitored parameters. The SCC had a positive significant correlation with contents of F, TP and Cas. In contrast, between SCC and content of lactose a negative significant correlation was found. Many studies show that the content of lactose can be reduced with mastitis and SCC increase. However, in our opinion a negative significant correlation between SCC and lactose content was not affected by intramammary infection, because in all cases the SCCs were lower than the thresholds for subclinical mastitis in sheep. Our opinion also largely supports the fact, that all correlations between SCC and pH, TA, CT and DMY were insignificant.

Keywords: *Sheep milk, Somatic cell count, Milk composition, Milk acidity, Clotting time,*

Introduction

The somatic cell count in sheep's milk is generally higher than in cow's milk and lower than in goat's milk and their count significantly affects the quality of milk and products made from it. Contemporaneously it must be emphasized that their count also affects the price of milk.

Most studies focused on somatic cell count show that the most significant non-infectious factors that influence increasing of somatic cell counts (SCCs) in sheep milk are parity, stage of lactation, time of year, herd and handling of ewes. According to Bergonier et al. (2003) non-pathological factors are responsible for variation of SCC in this milk between 40 x 10^3 and 100 x 10^3 cells/mL. Nevertheless, SCC is also a good indicator of the existence of subclinical mastitis, whereby subclinical infection may result in significant losses of milk yield and changes in milk composition (Gonzalo et al., 2002; Leitner et al., 2004). In the United States the limit for sheep milk is below 1 000 000 SCC/mL (Paape et al., 2007), whereas there is no legal limit for this milk in European Union. Nevertheless, Bianchi et al. (2004) reported the limit for subclinical mastitis in sheep at level of 500 000 SCC/mL and Pirisi et al. (2007) stated that in Sardinia is used an incentive payment for sheep milk with lower SCC than 1 000 000/mL.

Many studies also show that the composition of sheep milk can be affected by a lot of factors such as nutrition, season, stage of lactation, and year while its composition also fundamentally affects milk coagulation properties (MCP) and the curd quality (CQ). Other important factors

that influence MCP and CQ are pH and titratable acidity of milk (Pellegrini et al., 1997; Jaramillo et al., 2008).
The main aim of our study was to evaluate relationships between somatic cell count (SCC) and selected qualitative parameters of sheep milk. Determination of daily milk yield (DMY) and effect of the stage of lactation (SL) on selected parameters were also an integral part of the study.

Materials and Methods

The study was carried out under operating conditions at a specialized organic sheep farm located in the Zlín region of the Czech Republic. Eighteen ewes of Lacaune (LC) breed on the second lactation were involved in the study.
The daily feed ration of ewes during the study consisted of pasture (*ad libitum*), organic oat (0.2 kg/ewe) and organic mineral lick (*ad libitum*). Throughout the whole experiment ewes were continuously kept on the pasture. During the study, all ewes were kept in one flock under identical conditions without any discernible differences in their nutrition or management.
Individual milk records and samplings were carried out after weaning of lambs, from May to September, on the mean 57, 92, 127, 162, and 197 day of lactation. Milk records were carried out from morning milking (6 a.m.) and evening milking (6 p.m.). Milk samplings were collected only from morning milking. Individual milk samples were cooled to 5–8°C and transported to the specialized milk laboratory at the Mendel University in Brno and to the accredited private Laboratory for Milk Analysis in Brno – Tuřany.
SCC was determined using fluoroopto-electronic apparatus BENTLEY 2500 (Czech State Standard EN ISO No. 13366-2). Fat (F) content was determined by Gerber's acidobutyrometric method (Czech Technical Standard ISO No. 2446). Total protein (TP) and casein (Cas) contents were determined using a PRO-MILK apparatus (Foss Electric, Denmark). Lactose (L) content was determined polarimetrically (Czech Technical Standard No. 570530). Active acidity (pH) was measured with the pH-meter WTW 95 with the probe WTW SenTix 97. Titratable acidity (TA) was determined by titration using the Soxhlet–Henkel method (Czech State Standard No. 570530). Clotting time was measured according to Berridge (1952).
Statistical analyses were performed using the STATISTICA software, version 12. ANOVA analysis was used to study the differences in all monitored parameters during lactation. To identify individual significant contrasts within the lactation Sheffe's test was used. To asses a level of the correlation coefficient among all particular variables Pearson's correlation was carried out. The differences were considered significant if $P<0.05$. Statistical analysis showed that SCC were normally distributed, therefore the actual SCC were not transformed to logarithm forms for further statistical analyses.

Results and Discussion

The stage of lactation (SL) had a significant effect on contents of all basic milk components and DMY (Table 1). These findings are consistent with data published by Matutinovic et al. (2011). In sheep it is well-known that as lactation progresses the contents of F, TP and Cas in milk increase and the DMY gradually decreases, when all these trends were also found in our study. The correlations between DMY and contents of F and TP were significantly negative in all cases (Table 2), which is in accordance with Ochoa-Cordero et al. (2002) and Mioc et al. (2009). In contrast to F and TP contents, the content of lactose (L) significantly decreased during lactation which is in line with Pugliese et al. (2000) and Matutinovic et al. (2011). During lactation the average L content ranged from 4.99 to 4.58% and these values are comparable with Kuchtik et al. (2008) and Kondyli et al. (2012). With regard to correlations

between L and F and L and TP, both of these correlations were significantly negative what is in line with Mioc et al. (2009).
The SL had not significant effect on pH, what is in line with Barron et al. (2001). All correlations between pH and the other parameters were also insignificant. Even though the values of titratable acidity (TA) increased during lactation from 9.0 to 10.0 ^{0}SH, the SL also had no significant effect on this parameter. However, the TA of sheep milk can be significantly influenced by protein content (Novotna et al., 2009), while the higher the TP content, the higher the TA and vice versa. The same trend was also found in our study. It seems interesting that the correlation between pH and TA in our study was insignificant, because Kuchtík et al. (2008) found out that this correlation is significantly negative.

Table 1.: Means, ranges of mean values and individual samples of SCC, BMC, pH, TA, CT and DMY throughout lactation and effect of the SL.

Trait	Mean	Range of mean values	Range of individual samples	SEM	Effect of SL
SCC (10^3/mL)	112.10	87.72 – 130.22	36.00 – 420.00	7.223	NS
Fat (%)	7.33	6.25 – 7.69	4.56 – 9.82	0.118	**
TP (%)	5.7	5.48 – 6.26	4.71 – 7.43	0.051	**
Casein (%)	4.26	4.02 – 4.76	3.21 – 5.68	0.049	**
Lactose (%)	4.76	4.58 – 4.99	4.16 – 5.28	0.027	**
pH	6.4	6.4 – 6.5	6.1 – 6.8	0.01	NS
TA (ºSH)	9.55	9.0 – 10.0	6.56 – 11.8	0.13	NS
CT (s)	164	143 – 188	102 – 411	4.6	**
DMY (L)	0.94	0.77 – 1.07	0.30 – 1.60	0.027	**

SCC: somatic cell count; BMC: basic milk compostion; TA: titratable acidity; CT: clotting time; DMY: daily milk yield; TP: total protein; SL: stage of lactation.
Significance levels: ** $P < 0.01$; NS: not significant.

Table 2: Correlations of all monitored parameters.

	SCC	Fat	TP	Casein	Lactose	pH	TA	CT	DMY
SCC	1.00	0.36**	0.36**	0.30**	-0.32**	-0.01	0.18	0.21	-0.15
Fat		1.00	0.33**	0.26*	-0.61**	-0.21	0.10	0.05	-0.42**
TP			1.00	0.82**	-0.23*	0.07	0.35**	0.42**	-0.29**
Casein				1.00	-0.15	0.04	0.26*	0.35**	-0.15
Lactose					1.00	0.09	-0.17	-0.13	0.31**
pH						1.00	0.13	-0.01	0.08
TA							1.00	-0.01	-0.26*
CT								1.00	0.13
DMY									1.00

SCC: somatic cell count; TP: total protein; TA: titratable acidity; CT: clotting time; DMY: daily milk yield; ** $P < 0.01$; * $P < 0.05$.

The SL had a significant effect on clotting time (CT), whereby its average time, except for the first sampling, extended with advanced lactation, what corresponds to Jaramillo et al. (2008). In our opinion, elongation of CT in our study was mainly affected by the gradual increase of the contents of TP and Cas during lactation, what is also confirmed by their significant positive correlations.
All ewes in our study were under permanent veterinary supervision and no clinical signs of mastitis were observed. This fact was reflected in relatively low both mean counts which ranged from 88 to 130 x 10^3/mL and their counts in individual samples which ranged from 36

to 420 x 10^3/mL during lactation, whilst the limit of SCC for subclinical mastitis, which was published by Bianchi et al. (2004), was not exceeded in any of the individual samples. Nevertheless, the SCCs in our study insignificantly grew as lactation advanced what is in line with Jaramillo et al. (2008). On the other hand Paape et al. (2007) and Matutinovic et al. (2011) reported a significant increase of SCC during lactation. In our opinion, the insignificant increase of SCC during the lactation could be linked with a reduced milk yield or a functional alteration of the mammary gland tissue caused by the shorter survival of epithelial cells that are supplied with fewer nutrients at the end of the lactation as it is published by Sevi et al. (1999). The SCC had a positive significant correlation with contents of F, TP and Cas, which is in line with the results published by Matutinovic et al. (2011). In contrast, between SCC and content of lactose a negative significant correlation was found which is in line with Nudda et al. (2003). In connection with the statement above, it should be noted, a lot of studies show that the content of lactose can be reduced with mastitis and SCC increase. According to Raynal-Ljutovac et al. (2007) the decrease in synthesis function of the mammary gland in case of mastitis results in lower lactose concentrations and also in a flow of minerals, sodium and chlorides, from blood to milk to maintain osmotic equilibrium. However, in our opinion a negative significant correlation between SCC and lactose content was not affected by intramammary infection, because in all cases the SCCs were lower than the thresholds for subclinical mastitis in sheep. Our opinion also strongly supports the fact, that all correlations between SCC and pH, TA, CT and DMY were insignificant.

Conclusions

As expected, the stage of lactation had a significant effect on contents of all basic milk components and daily milk yield. On the other hand, this factor had no significant effect on somatic cell count, pH and titratable acidity of sheep milk. The somatic cell counts in our study were relatively low both in mean counts and their counts in individual samples. The SCC had a positive significant correlation with contents of fat, total protein and casein. In contrast, between SCC and content of lactose a negative significant correlation was found. However, in our opinion a negative significant correlation between SCC and lactose content was not affected by intramammary infection, because the SCCs were lower in all cases than the limit for subclinical mastitis in sheep. Our opinion is also strongly supported by the fact, that all correlations between SCC and pH, TA, CT and DMY were insignificant. Finally, despite the relatively low number of ewes in our study, the results of our study suggest that the limit for subclinical mastitis in sheep at level of 500 000 SCC/mL is realistic.

Abstract
Animal production is an agriculture sub-sector together with crop production, fisheries and forestry. Agriculture is at the centre of the debate on sustainability and sustainable development. However, such a debate has, generally, two weaknesses; it ignores the contribution of livestock in agriculture and focuses on agriculture production rather than the whole food system. Therefore, the objective of this review is to analyse the relationship between livestock and sustainable food systems and to explore its implications in the context of the 2030 Agenda for Sustainable Development, including the Sustainable Development Goals (SDGs). After introducing the concept of sustainable food systems and providing an overview on the 17 SDGs, the paper explores linkages between agro-food systems and the SDGs. The analysis of the role of livestock in the context of the SDGs – both positive contributions and negative impacts as well as trade-offs – focuses on SDG 1 (No poverty), SDG 2 (Zero hunger), SDG 6 (Clean water and sanitation), SDG 13 (Climate action) and SDG 15 (Life on land). The review shows that livestock, sustainable food systems and the SDGs are strongly related. It also points out that intensive livestock systems, which are dominant nowadays especially in some developed countries, may jeopardise the achievement of the SDGs. Therefore, the paper argues that de-intensification – e.g. through conversion to environmentally-friendly livestock systems such as organic farming – can allow keeping the multifaceted and multidimensional benefits of the livestock sector while decreasing its negative externalities. This will contribute to the effective implementation of the 2030 Agenda as well as other regional agendas (e.g. CIHEAM Strategic Agenda 2025 in the Mediterranean region).

Keywords: *Climate change, Food security, Livestock, Sustainable Development Goals, Sustainable food systems.*

Introduction
Agriculture (crop production, animal production, fisheries and forestry) is central in the discussion on sustainable development. Meanwhile, there is an ongoing debate about the relation between livestock (including livestock products) and the sustainability of food systems (FAO, 2018a; HLPE, 2016a) from the environmental, economic, socio-cultural and nutrition-health points of view. This debate has become particularly relevant in the context of the 2030 Agenda for Sustainable Development and the related Sustainable Development Goals (SDGs) (United Nations, 2015) as well as other regional agendas such as the CIHEAM Strategic Agenda 2025 for the Mediterranean Region (CIHEAM, 2016). Indeed, it is widely recognized that there can be no achievement of SDGs without making transition towards sustainable food systems. This implies that the entire food chain - from production to consumption through processing and distribution - should become more sustainable in order to yield outcomes that contribute to a better world. However, it is not clear the role that

livestock will play in this sustainability transition journey. Therefore, the main objective of this review is to analyse the relationship between livestock and sustainable food systems and to explore its implications in the context of the SDGs.

Livestock in food systems

Livestock is commonly referred to all those domesticated animals raised in agricultural settings to produce benefits for human beings. Humans obtain labour from these animals and commodities such as meat, milk, eggs, leather, fur and wool (Encyclopaedia Britannica, 2019). The following table (*Table 1*) shows the amount of actual livestock's main species in the world. It is clear that Asia is the most important continent in terms of livestock production.

Table 1. Live animals, 2017.

	Cattle	Sheep	Goats	Pigs	Horses
World (Million head)	1,491	1,202	1,034	967	60,6

Source: FAO (2019).

Livestock is an important component of food systems. Indeed, according to HLPE (2014), "*A food system gathers all the elements (environment, people, inputs, processes, infrastructures, institutions, etc.) and activities that relate to the production, processing, distribution, preparation and consumption of food, and the outputs of these activities, including socio-economic and environmental outcomes*" (p. 29). Thus, a *food system* is intended as the sum of all the diverse elements and activities which, together, lead to the production and consumption of food as well as their interrelations (HLPE, 2014). The next step is to achieve a *sustainable food system* (SFS) defined as "*a food system that ensures food security and nutrition for all in such a way that the economic, social and environmental bases to generate food security and nutrition of future generations are not compromised*" (HLPE, 2014:31). The main objective of this definition is that a sustainable food system must ensure today's and tomorrow's food and nutrition security; if a food system does not ensure food security and adequate nutrition, it cannot be called sustainable. Livestock affects all dimensions of sustainability (environmental, economic, socio-cultural and nutrition-health) in food systems and diets (Dernini *et al*., 2013; Dernini *et al*., 2016; HLPE, 2016a; Layman, 2018).

Food systems in the context of the Sustainable Development Goals (SDGs)

The 2030 Agenda for Sustainable Development is a plan of action for people, planet, prosperity, peace and partnership (United Nations, 2015); it consists of 17 SDGs, 169 targets and 232 indicators (*Table 2*). The goals and targets aim to stimulate actions in areas of critical importance for humanity and the planet. Food and agriculture, as the prime connection between people and the planet, can help achieving the multiple SDGs. Indeed, according to FAO (2018b), "*Sustainable food and agriculture have great potential to revitalize the rural landscape, deliver inclusive growth to countries and drive positive change right across the 2030 Agenda*" (p. 7). Chaudhary *et al*. (2018) argue that food systems are at the heart of at least 12 of the 17 SDGs. Likewise, Caron *et al*. (2018) put that "*evidence shows the importance of food systems for sustainable development: they are at the nexus that links food security, nutrition, and human health, the viability of ecosystems, climate change, and social* *justice*" (p. 38). Even though, what is needed to emerge is a strategic narrative linking climate, agriculture and food, and calling for a deep transformation of food systems at large scale. For that, agriculture and food policies should be aligned to the 2030 Agenda (Caron *et al.*, 2018).

Table 2. Sustainable Development Goals (SDGs), targets and indicators.

No.	SDGs Short Name	SDGs Full Name	Number of Targets	Number of Indicators
1	No poverty	End poverty in all its forms everywhere	7	12
2	Zero hunger	End hunger, achieve food security and improved nutrition and promote sustainable agriculture	8	14
3	Good health and well-being	Ensure healthy lives and promote well-being for all at all ages	13	26
4	Quality education	Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all	10	11
5	Gender equality	Achieve gender equality and empower all women and girls	9	14
6	Clean water and sanitation	Ensure availability and sustainable management of water and sanitation for all	8	11
7	Affordable and clean energy	Ensure access to affordable, reliable, sustainable and modern energy for all	5	6
8	Decent work and economic growth	Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all	12	17
9	Industry, innovation and infrastructure	Build resilient infrastructure, promote inclusive and sustainable industrialization and foster innovation	8	12
10	Reduced inequalities	Reduce inequality within and among countries	10	11
11	Sustainable cities and communities	Make cities and human settlements inclusive, safe, resilient and sustainable	10	15
12	Responsible consumption and production	Ensure sustainable consumption and production patterns	11	13
13	Climate action	Take urgent action to combat climate change and its impacts	5	8
14	Life below water	Conserve and sustainably use the oceans, seas and marine resources for sustainable development	10	10
15	Life on land	Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss	12	14
16	Peace, justice and strong institutions	Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels	12	23
17	Partnerships for the goals	Strengthen the means of implementation and revitalize the global partnership for sustainable development	19	25

Livestock in the context of the Sustainable Development Goals

The following analysis focuses on 5 SDGs that are considered relevant in determining the impacts (positive, negative) of livestock on the implementation of the 2030 Agenda, namely SDG 1 (No poverty), SDG 2 (Zero hunger), SDG 6 (Clean water and sanitation), SDG 13 (Climate action) and SDG 15 (Life on land).

Livestock and SDG 1 (No poverty)

Since 1990, extreme poverty rates have decreased considerably, but the number of people living in extreme poverty globally remains unacceptably high. Studies reflect that 10.7 percent of the world's population in 2013 were living under the international poverty line (World Bank, 2017). According to the World Bank (2011), one in five people has to live with less than $1 a day. Poverty is still a rural phenomenon to a large extent; nevertheless, rural areas and their people have not received appreciation for their contributions to the achievement of sustainable development. Moreover, the health and well-being of rural agroecosystems and communities are considerably interlinked with the well-being, resilience and food security of cities (Anderson, 2015).

Livestock has been one of the fastest-growing agricultural sectors in developing nations and it is widely believed that agricultural growth has helped in decreasing the levels of poverty (Loayza and Raddatz, 2010). Indeed, Robinson *et al*. (2011) estimated that in 2010 the livelihoods of more than half a billion depended entirely or partially on livestock production. Livestock is essential in helping rural households to achieve their well-being expectancies (FAO, 2018; Herrero *et al*., 2013) as it affects all the assets and capitals of rural households. First, it enhances human capital by providing access to food, continued good health, life quality and labour. Second, it builds social capital, consolidating the cultural diversity and heritage of some ethnic groups and populations. Third, it contributes to the reserves of the natural capital that provides the resources and services needed to maintain and improve livelihoods. Fourth, it increases physical capital, providing transport, draught power and alternative energy for households to support and improve their productivity. Fifth, it improves the financial capital of families, providing an economic confidence for securing livelihood goals (FAO, 2018). Livestock is important not only for developing countries. For instance, in the European Union (EU) the livestock sector (meat, milk, eggs) makes up 40% of the agricultural production value. This part of the livestock market is nearly half (48%) of total EU's agricultural activity, with an estimated 130 billion EUR output value annually, and creates almost 30 million jobs (Animal Task Force, 2016).

Livestock and SDG 2 (Zero hunger)

The most recent report on the *State of Food Security and Nutrition in the World* (FAO *et al*., 2018) shows that the number of undernourished people has been growing and was estimated to nearly 821 million in 2017 (17 million more than in 2016), so one out of every nine people in the world. Moreover, food insecurity contributes to overweight and obesity and the three burdens of malnutrition (undernutrition, overweight/obesity and micronutrient deficiencies) coexist in many countries (FAO *et al*., 2018). Indeed, 2 billion people lack the essential nutrients they need to carry out healthy lives, while the number of overweight people has reached more than 1.9 billion adults, with more than 600 million classified as obese (HLPE, 2016) and the livestock sector (and animal-source foods) is blamed for these daunting figures (e.g. Wang and Beydoun, 2009). However, the livestock sector can also play a key role in ending hunger and malnutrition by helping the communities in different aspects and levels. At the household level, the main contribution of livestock is to well-nourish all household members, helping them to be healthy and to be able to improve their personal economies. It has been proved that livestock products contribute to the global human diet with 33 percent of protein intake and 17 percent of calorie intake (Rosegrant *et al*., 2009). Animal-source foods are very rich in nutrients, sources of energy, high-quality protein and essential micronutrients – such as vitamin B12 or calcium – which are difficult to obtain from only plant-based foods to keep a healthy diet (Murphy and Allen, 2003).

Livestock and SDG 6 (Clean water and sanitation)
Agriculture withdraws around 70 percent of all available freshwater, and livestock production uses approximately 30 percent of that quantity (Ran *et al*., 2016). Agricultural pressures on water quantity and quality come from all agriculture sub-sectors (crops, livestock, aquaculture) (Mateo-Sagasta *et al*., 2017). As for livestock, the total number has more than tripled (from 7.3 billion in 1970 to 24.2 billion units in 2011) (FAO, 2019) and that significantly increased the use of natural resources, including water. Nutrient runoff and leaching from livestock waste have serious detrimental effects on coastal areas. Therefore, the improvement in waste management on livestock farms can be a cost-effective way of reducing river-based nutrient loads, which often end up in marine systems and contribute to coastal eutrophication (Arheimer *et al*., 2004). Nevertheless, environmental services provided by livestock can be promoted through specific payments while water pollution can be avoided through better manure management (FAO, 2018). By carrying out these two main aspects, it should be possible to achieve a sustainable food system.

Livestock and SDG 13 (Climate action)
The UN recognised that climate change is the single biggest threat to development (FAO, 2018; United Nations, 2019). Evidence shows that 2016 was the third hottest year recorded in a row. That same year, the average CO_2 concentration in the atmosphere surpassed the unrealistic amount of 400 parts per million, a level never before reached in recorded history (more than 650,000 years). The current increase rate of greenhouse gases (GHG) is more than 100 times faster than when the last ice age ended (World Meteorological Organisation, 2017). These data should be shockingly enough to start trying to reverse the current situation.
Actually, the climate change impacts on agriculture and the implications for food security are alarming, because its symptoms will disproportionately fall on the poorest and most vulnerable people and countries. Climate change impacts livestock directly (the increasing temperatures also increases stress on animals and their mortality) and indirectly (by reducing the quantity and quality of feed and fodder, increasing the incidence of animal diseases) (FAO, 2018). Livestock sector contributes significantly to climate change in that direct livestock's GHG emissions, from manure and enteric fermentation, represented 2.4 gigatons of CO_2 equivalent in 2010, about 21 percent of total emissions from agriculture, forestry and other land uses, or about 5 percent of total anthropogenic GHG emissions (IPCC, 2014). Gerber *et al*. (2013) argue that global GHG emissions from livestock are very significant, representing 14.5 percent of all anthropogenic emissions.

Livestock and SDG 15 (Life on land)
Across the globe, natural resources are deteriorating, ecosystems are under stress and biological diversity is being lost (Millennium Ecosystem Assessment, 2005). The food sector is, worldwide, a dominant user of natural resources (UNEP, 2016). That is why unsustainable agricultural production consumes a large fraction of the world's available fresh water, and has contributed to increase deforestation, biodiversity loss, land degradation, and conversion of natural habitats. Changes in land use, including deforestation, result in the loss of valuable habitats, water pollution, land degradation, soil erosion and the release of carbon into the atmosphere. Such damage is mainly due to the conversion of forest or rangelands to other land uses such as agriculture (including pastures and land for feed production) and

infrastructure development (FAO, 2018). While the livestock sector plays a part in biodiversity reduction, land degradation and deforestation (FAO, 2006), it also provides invaluable services that promote sustainable use of terrestrial ecosystems, combat desertification, reverse land degradation and avoid biodiversity erosion (FAO, 2018).
In order to ensure sufficient food production without affecting ecosystem health, there is a need to make transition towards agro-ecological approaches such as organic farming. Indeed, organic agriculture – including organic animal production – delivers significantly higher public goods (e.g. soil fertility, biodiversity, quality of surface and drinking water) than conventional agriculture and has, consequently, great potential to contribute to the achievement of the SDGs (IFOAM, 2016; Setboonsarng and Gregorio, 2017).

Conclusions

Livestock, sustainable food systems and the SDGs are strongly related, and the contribution of livestock to both the sustainability of food systems and the SDGs is widely recognised. On the other hand, the intensive livestock system, which is dominant nowadays especially in industrialised countries, may jeopardise the achievement of the SDGs. De-intensification and "extensification" of livestock will contribute to keep the environmental, social, nutritional and economic benefits of the livestock sector and to decrease its externalities, thus contributing to the effective implementation of the 2030 Agenda for Sustainable Development. Finally, the conversion to organic livestock farming and other forms of environmentally-friendly livestock systems, can be considered as a strategy for the de-intensification and greening of the livestock sector, which is strongly necessary for the coming times.

Abstract

The present study aims to study the effect of storage time and temperature on the semen quality of adult rabbits of the same age of the ITELV 2006 strain. In order to achieve our goal, 04 experiments are conducted to evaluate the semen quality of 10 adult rabbits. The semen samples are mixed the individual's ejaculation analysis and divided into fractions, and then diluted in a Tris diluent. They are then kept at four different temperatures for 96 hours. Samples are taken after 24, 48, 72 and 96 h. The experiment is repeated 4 times during 1 month at a rate of once a week. The microscopic parameters of ejaculation are evaluated before and after the preservation process. The results of the analysis showed that the percentage of motility and vitality of spermatozoa in fresh semen is 82.86% ± 7.82, 73.69% ± 1.29 respectively. For the conserved semen and for the same parameters, a decrease in the motility and vitality values is observed with the conservation time ($p<0.05$). For the storage temperature, the semen kept at 15 ° C for 24h has the best values compared to other temperatures (61.75% ± 2.05 and 66.5% ± 1.12 respectively for motility and vitality, $p<0.05$). We record a zero motility and vitality for the semen kept at 4 ° C from 72h.

Key words: *spermatozoa, refrigeration, Tris-based extender, vitality, motility.*

Introduction

Despite the widespread use of Artificial Insemination (AI) in large rabbit farms in several countries around the world, it has not become a common practice in Algeria. A limiting factor for a more extensive practical application is related to the conservation of the semen. The current practice of using freshly diluted sperm in a few hours following collection is mainly limited to AI at the farm where the male is located, resulting to such high conception rates as those obtained with natural mating. Short life imposes considerable stress on rabbit AI, as fast delivery is essential. Since frozen semen is currently not suitable for routine AI in commercial rabbit production (Morrell 1995 and Castellini 1996). The interest in preserving rabbit semen for a period of 24-72h has been the subject of several trials (Alvarino et al., 1996, Gottardi, 1993, perrier, theau-clément et al 1998, Santa Maria et al, 1989). Badù et al 2004, have shown that the semen kept 24h at 5 ° C in a saline solution (Tris- EDTA- citric acid) does not affect the mobility nor the straightness of the displacement of the cells. The storage temperature and its duration play an important role in sperm survival (Carluccio, and al., 2004) Temperatures of 5 ° C to 25 ° C are suitable for the preservation of rabbit sperm for 72 h (Johinke, D. and al., 2014; López, FJ and Alvariño, JMR 1998; Roca, J., and al., 2000). Mathur and al. (1992), Gottardi (1993) and Lopez and al. (1996) found that a storage temperature of 15 to 19 ° C is the most favorable for sperm survival. Sperm refrigerated and stored for 24 to 72 hours may facilitate their transport and subsequent widespread use of artificial insemination in rabbits while preserving the fertilizing capacity of sperm. In order to improve the management of reproduction, the objective of this study is to evaluate the effect of different storage times at different temperatures on the quality of the ITELV 2006 synthetic strain semen. This strain is created in 2003 as part of a breeding program cooperation between INRA and ITELV; it is obtained by an initial cross between the Algerian local population and the INRA 2666 strain (Gacem and Bolet 2005).

Materials and Methods

At the level of the animal department of the Department of Agricultural Sciences and Biotechnologies, Hassiba Ben Bouali University of Chlef, Algeria, 10 adult male rabbits of the synthetic hybrid strain ITELV 2006 brought from the Baba Ali Breeding Technical Institute of Algiers, aged 7.5 to 8 months, so at the time of sexual maturity. Indeed, sexual maturity, defined by the time when the number of spermatozoa harvested per day no longer increases, would be reached around the age of 32 weeks (Amann and Lambiase 1967). However, spermatozoa have been present in the ejaculation at puberty as early as 16 weeks of age (Martinet 1974). The average weight at the beginning of the test is 3.70 ± 0.13 kg and the same housing conditions are used. During the experimental period all animals receive, voluntarily, a commercial feed in the form of granules, containing maize, soybean meal, mill products, calcium, phosphates, amino acids, trace elements, poly vitamins, antioxidant, folic acid, oil soybean and alfalfa (Table 1) and watered ad libitum and placed in individual wire cages (75 cm long, 46 cm wide and 28 cm high) inside an air-conditioned building. The livestock building is a concrete room, with an area of 220.80 m^2 and a height of 4m. It consists of two separate rooms, one for the breeding of animals and the other in the form of a laboratory for carrying out various analyzes. The two dirty ones are opened in the light of the day by several lateral windows, having a system of cooling.

Table 1: Chemical composition of the standard feed

Component	Content. (% as is)	Reference of the method of analysis
Dry matter	91.42	NA 1291-1994
Mineral matter	7.51	NA 650 - 1994
Raw protein	14.5	NA 652-1992
Crude cellulose	9.49	NA 6138 -1991
Fat	3.38	NA 654 -1992
Calcium	0.89	NA 653 - 1992
Phosphorus	0.60	NA 657-1992

The sperm collection is carried out in a period of one month (March 2018) according to the following protocol: two successive ejaculates a single day a week. An interval of 10 min separated the 2 successive samples. The harvest of 2 consecutive ejaculates per day of collection and the choice of collection frequencies are initially motivated by the bibliographic knowledge. Males are trained to collect sperm using the artificial vagina as early as 5 months of age (Garcia and al 2004, Garcia-Thomas and al 2006b, Lavara and al 2008, Theau-Clément and al 2009). No sexual preparation is applied to the male before collection. A refusal of harvest is recorded if the male could not be harvested within ten minutes of contact with a first rabbit as well as with a second (Theau-Clément and al 1991 and 2009). Sperm collection is performed using an artificial vagina and in the presence of a receptive female teaser (Boussit 1989).

The methods of sperm analysis are as follows: Once the sperm has been collected, the total volume of ejaculate collected is measured by direct reading on the graduated tube used for collection. If the sperm collected contains gel, the gel is removed using a Pasteur pipette to determine the frost-free volume. Sperm pH is measured using a pH meter. Before dilution, macroscopic analyzes of each ejaculation were performed to assess the color and volume of the sample; Only white ejaculates had a volume greater than 0.25 ml, and had at least 70%

motility are used for the study. Then the mass and individual motility of spermatozoa are determined under a microscope. Mass motility is appreciated by placing a drop of pure sperm between slide and lamella observed at magnification (x10). A note is attributed to the movement of the mass of spermatozoa observed according to the Petitjean grid (1965) (Boussit 1989) ranging from 0 to 9. Individual motility is assessed after dilution of sperm in 1cc of saline. A drop of semen (diluted sperm) is observed between slide and coverslip at a magnification (x 40). The type of individual movements of spermatozoa is noted using the Andrieu (1974) scale (Boussit 1989) ranging from 0 to 4. The percentage of dead spermatozoa is determined by the preparation of a smear using eosin-nigrosine vital staining: a drop of sperm diluted in saline is mixed with a drop of dye, then the mixture is gently spread on a blade with a coverslip and dried in the open air (Baril and al 1993). Then it is observed under a microscope at magnification (x 40); 100 spermatozoa are counted, from which are estimated the percentage of colored spermatozoa corresponding to the dead spermatozoa whose damaged membrane is permeable to the pink coloring, whereas the living spermatozoa with their functional membranes do not diffuse the dye and therefore remain colorless (Boussit 1989). The percentage of abnormal spermatozoa is studied on the same slide used to count living spermatozoa. 100 spermatozoa are randomized from which abnormal spermatozoa are distinguished (Boussit 1989). The spermatozoa concentration (in million / ml) is determined using a Thoma cell type hemocytometer from a diluted drop of semen. Counting is performed under the microscope at × 40 magnification (Boussit 1989). All ejaculates are pooled to eliminate the differences, then the heterosperm samples are diluted (1/10) in a Tris diluent and the diluted sperm samples are divided into four equal fractions. was cooled gradually from 37 ° C to 5, 10, 15 and 20 ° C for 120 minutes (Mocé, E. and Vicente, JS 2009) and stored for up to 96 h. The evaluation of viability and motility of spermatozoa are determined at 24, 48, 72 and 96 h after the start of cooling This experimental procedure is repeated four times (once a week). In the experiment, all measurements are made within 4 weeks directly after harvest, 24, 48, 72h and 96h. Our statistical study of the obtained data is processed by a software XLstat 2016 for the calculations concerning the descriptive statistics. The characteristics of ejaculate are then studied using a fixed-effect model of variance analysis including the effects of storage temperature, shelf life and their interactions.

Results and Discussion

The color for all the results found in rabbits. According to the Roca and al (1993) sperm color chart, ranging from 0 to 3 (pearly white or ivory white sperm), a score of 3.0 is assigned for all ejaculates (Table 2). The average volume of all collections in our experiment is 0.48 ± 0.11 ml, lower than that collected in different breeds (Californian, New Zealand White and Chinchilla of Mexico) between 32 and 48 weeks of age (1.15 ml) (Salcedo-Baca and al 2004). According to Boulbina and al (2011) in the local Algerian rabbit, the total volume collected between the 24th and 33rd week of age is estimated at 1.2 ml. Furthermore, in hybrid rabbits, aged between 3 and 18 months, the mean sperm volume was 0.92 ml (Roca and al 2005). The pH of sperm collected during the experiment averaged 6.86. This value is considered normal and comparable to that reported by Brun and al (2006). A variability in sperm pH is revealed by the literature data between the different strains and races studied (from 6.94 to 7.63) (Garcia-Tomas and al 2006a, Brun and al 2002a, Brun and al 2009) . The measurement of the pH at the pH meter must be immediate because the semen is rapidly acidified following the formation of lactic acid, resulting from the use of sugars by the spermatozoa (Alvarino 1993, Arencibia and Rosario 2009). The concentration shows an average of 502 ± 29 million spermatozoa which is close to the values described by Boiti (2005) and Nabi (2013) for the same age. Our results are weaker than those recorded by Bencheikh (1993), Brun and al (2002), Castellini and al (2003), Theau-Clément and al (2009) and Brun and al (2006) in the L line (634x106 spermatozoa/ ml) and line H (738 x 10^6 spermatozoa / ml). Indeed, Boulbina (2011) found a higher mean value (642 x 10^6 spermatozoa and 735x10^6 spermatozoa / ml) in rabbits harvested from the 24th week of age to the 33rd age. Furthermore, Safaa and al (2008) indicate concentrations of 703 × 10^6 spermatozoa / ml for the Black Baladi breed and 590 × 10^6 spermatozoa / ml for the White New Zealand breed (in Egypt). However, significantly lower concentrations, of the order of 243 x 10^6 spermatozoa / ejaculate, are revealed in various strains selected by INRA (1077, 2066, 2666 and 1001) (Theau-Clément and al 2003; 2009) and of the order of 245x10^6 spermatozoa / ml for both lines C and R as reported by Garcia-Tomas and al (2006a). The mean scores of mass and individual motility were respectively 5.21 ± 0.77 out of 9 and 3.36 ± 0.56 out of 4. The whole of the ejaculates has an average percentage of spermatozoa abnormal of 14.4 ± 4.05%. Nevertheless, the average scores of mass and individual motility are low, below the threshold of good mobility (mass motility: appearance of waves (≥ 6/9) and individual motility: rapid progression (≥3 / 4) and desirable for inseminations (Boussit 1989). This weakness of motility can be a specific character of the strain, as it could be explained by the small number of observations recorded in a potentially short duration. The spermatozoa in sperm of synthetic rabbits are characterized by a lower mass motility than that measured in rabbits of different origins (Bencheikh 1995, Theau-Clément and al 2003, Brun and al 2006 and 2009). On the other hand, their individual motility is sometimes superior, sometimes weaker than those reported by the bibliographic data and this according to the genetic origin of the rabbit (Bencheikh 1995, Garcia-Tomas and al 2006a). Boulbina (2011) found a low rate of spermatozoa mobility in the local rabbit (64.2%) and 74.8% at older ages in the same population (between 24 and 33 weeks). Brun and al. (2006) reported a rate of 76% using males of selected lines on growth. The mobility of spermatozoa seems to improve with age (Salcedo-Baca and al 2004). In the rabbit, studies indicate that good mass motility of spermatozoa accompanies a good pregnancy rate (Brun and al 2002b). Whatever the characters considered (volume, motility, concentration), lower values are obtained than those recorded by Bencheikh (1993), Brun and al (2002), Castellini and al (2003), Brun and al (2006) and Theau-Clément and al (2009) (France). In fact, Boulbina (2011) found higher average values, namely volume (0.86 ml), mass motility (7.68), individual motility (3.57), and concentration (735x10^6 spermatozoa).). These differences in volume and sperm concentration appear to be related to the genetic origin of the rabbits and the selection program to which they would be subjected. It is important to note that the methods used by these different studies are based on observation and counting, which is likely to be an additional source of variability in the results.

Table 2. Macroscopic and microscopic features of fresh semen.

	N	*avg*	*ETM*	*Distr*
Color	80	3.00	0.00	3—3
pH	80	6.86	0.12	6.66—7.20

Percentage of live spz	80	73.69	1.29	70—76
con x10^6 spz/ml	80	502	28.9	437-564

n: number of ejaculates; avg: average; ETM: standard deviation of the mean; Distr: extent of distribution of spermatozoa per male; con: concentration; spz: spermatozoa; n: number of ejaculates; avg: average; ETM: standard deviation of the mean; Distr: extent of distribution of spermatozoa per male.

Mean values and global standard deviations of the different criteria for sperm analysis after storage are shown in Table 3.

The results obtained allow us to deduce that the overall motility decreases over the conservation time, from 5.21 ± 0.77 to 24h vs 0 to 96h, while variable values are recorded for the storage temperatures with deterioration of the characteristics studied from 72h, for the deferent storage temperature.

The effect of storage time and temperature on the motility and vitality of the semen is shown in Figure 1, the results showed that all spermatozoa parameters are decreased with storage time (P <0.05), regardless of the refrigeration temperature used. This is comparable to the El-Gaafary (1994) study, using a Tris-yellow diluent, which found that sperm are cooled and stored at 5°C for 24 h. had an average motility of 45% and dropped to 25% after 48 hours. This sharp decrease in sperm viability during the entire storage time may be due to the cooling temperature. Temperature as a cause of disturbance of rabbit spermatozoa has not been established, however studies comparing various conservation temperatures of rabbit sperm conclude that 15 ° C is more appropriate than 5 ° C (Roca and al., 2000). .

(a, b, c, d , e , f , g , h , i) in the same row and for the same parameter, the assigned values of the same letter do not differ significantly (P> 0.05).

There are interactions between temperature and storage time (P <0.05) on all evaluated parameters. After 72 hours of storage, the quality of the semen stored at 15 ° C provided better results with significant deference (p <0.05) for all parameters studied compared to other temperatures used. However, the in vitro study by J. Roca (2000) demonstrated that 15 ° C may be a suitable temperature for storing rabbit semen when Tris buffer extensions are used. Castellini, 1996 concluded that inorganic buffers have limited buffering capacity while organic buffers, such as Tris, are more suitable for storage of rabbit sperm at low temperatures.

The effective use of chilled semen for AI depends on the vitality and motility of the sperm after storage. In our study the comparison of the quality of the semen kept at 4 ° C and 20 ° C in the same storage time, showed no significant difference (P> 0.05) between the spermatozoa examined for the viability parameters and motility.

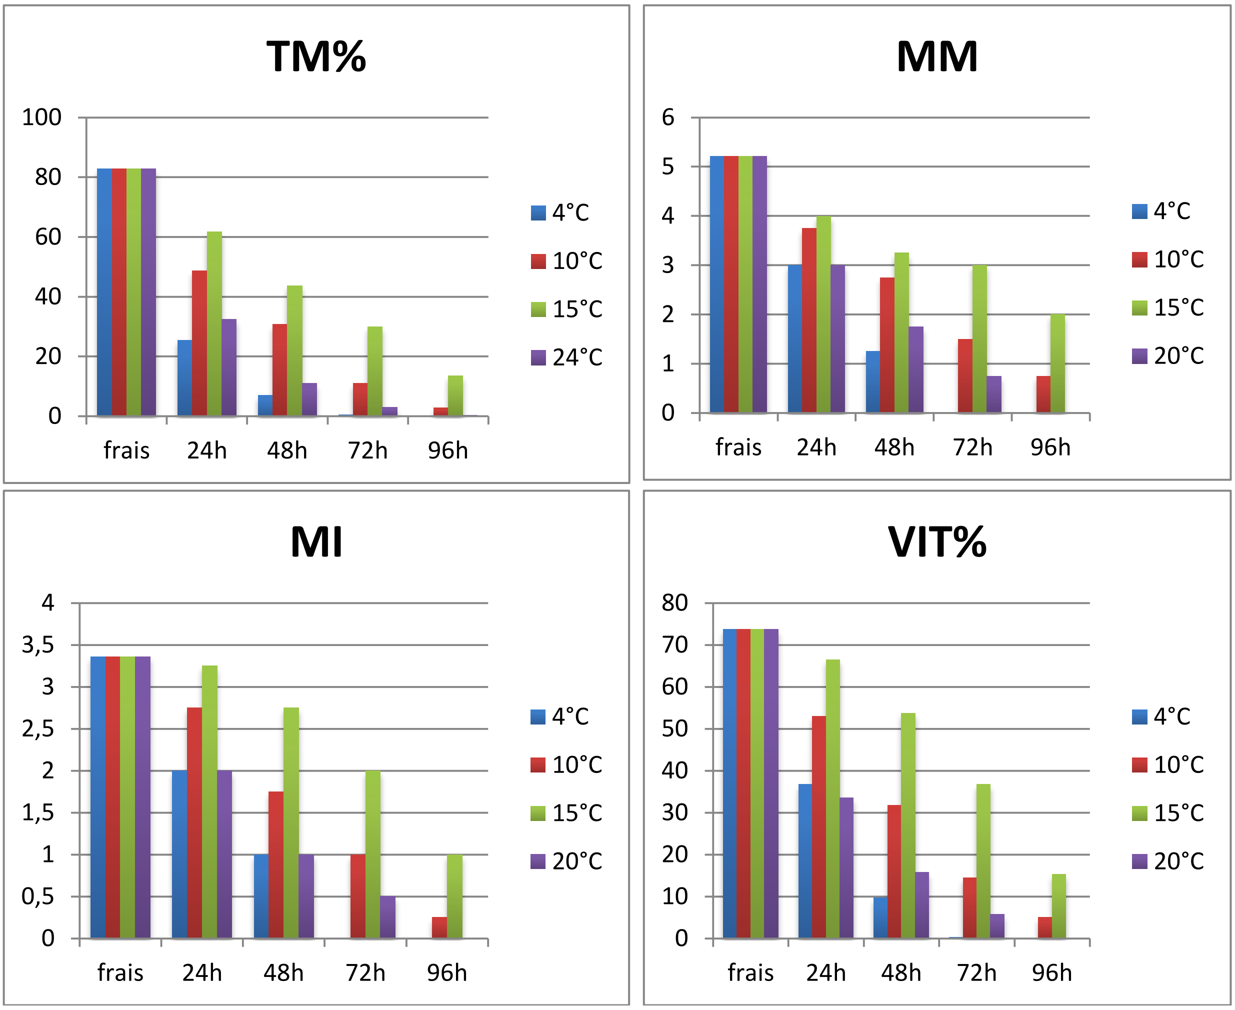

Figure 1: Evolution of semen variation parameters during the storage period.

The quality of spermatozoa is higher (P <0.05) for semen's kept for 24 hours compared to other durations. Spermatozoa examined at 96 h shows the lowest parameters (P <0.05).
Previous studies to evaluate the fertility of sperm stored in rabbits have been conducted under experimental conditions (El-Gaafary 1994, Maertens and Luzi 1995). Whereas the conception rate did not decrease when the semen was stored at 20 ° C for 6 h after dilution in a commercial diluent based on Tris Maertens and Luzi (1995), while El-Gaafary (1994) showed a fall birth rates when sperm were stored at 5 ° C for 24 and 48 h after dilution in a Tris-yellow diluent.
Sperm storage temperature is an important factor in maintaining the fertility of rabbit spermatozoa (López and al., 1996) and the temperature of 15 ° C seems to be better than the temperatures of 4 ° C, 10 ° C and 20 ° C. ° C with a shelf life of no more than 72h and the use of Tris buffer extensions.

Conclusion

It can be concluded that Tris buffer diluents are effective for dilution and storage of rabbit sperm at 15 ° C for 72h. The effect of storage time and temperature on semen motility and vitality shows that all spermatozoa parameters are decreased with storage time (P <0.05), regardless of temperature refrigeration used.
Nevertheless, after 72 hours, the quality of the semen kept at 15 ° C provided better results with a significant deference (p <0.05) for all the parameters studied compared to the other

temperatures used, this quality being higher (P <0.05) for semen's kept for 24 hours compared to other durations. So we can never go back to the original quality of the fresh semen.
The comparison of the quality of the semen kept at 4 ° C and 20 ° C in the same storage time, shows no significant difference (P> 0.05) between the spermatozoa examined for viability and motility parameters.
The temperature of 15 ° C seems to be better than the temperatures 4 ° C, 10 ° C and 20 ° C with a shelf life not exceeding 72h and the use of Tris buffer extensions, which allows to conclude that are effective for dilution and storage of rabbit semen at 15 ° C for 72h.

CHARACTERISTICS OF BASIC BEHAVIOURAL FEATURES OF 'HORNLESS HEREFORD' LACTATING COWS RAISED ON A NATURAL GRASSLAND

Nikolay MARKOV*

Abstract

A study was conducted on the main elements of the behaviour of lactating beef cows of 'Hornless Hereford' breed with their calves at the age 5-6 months on a natural pasture in the region of Troyan, Bulgaria. The pasture is situated at 386 m above sea level on a flat terrain with a local grassland. The meteorological indicators characteristic of the late spring were recorded. The behavioural reactions were examined by chronometry, such as: grazing, having a rest, lying and ruminating, moving, water intake, defecation, nursing of calves. It was found that cows were grazing from 5.36 to 5.51 hours on average during the experiment and the calves were suckling 4-6 times a day and 2 times at night, respectively. The time used for grazing is comparable to that recorded under other climatic conditions, grazing composition and meat cattle breeds. The physiological state, the climate elements, the alimentary conditions and the raising system had an impact on the behavioural reactions of lactating beef cattle. Animals tested were characterized by imitating behaviour.

Keywords: *Pasture, cows, behaviour, 'Hornless Hereford', grassland*

Introduction

Grazing on natural pastures of beef cattle is controlled by the farmer. It is the result of applied agro technical events that determine the amount (Iliev et al., 2017) and quality (Todorova and Churkova, 1998; Nikolova, 2012; Bozhanska et al., 2017) of the grassland that is used.

The cow grazes no more than 8 hours, as the immediate grass picking is about 5 hours on average. The rhythm of jaw movement in beef cows is 50 movements per minute on average (Wuazen, 1959; Roussev and colleagues, 1978; Nowicki 1981; Lubritz et al., 1989; Baskin and Chikurova, 2014).

Phillips (2002) found that beef cows are taking about 50000 bites of grass for twelve hours, as the bite frequency depends on the quality composition of the grass bite. When the grassland length is greater than 10 cm, the cow takes a pinch of 25-30 g of dry matter per a minute.

According to Albright and Arave (1997), cattle show increased activity at sunrise and sunset.

Hancock (1950) discovers and investigates genetically determined differences in the amount of grass, which was grazed, during twenty-four hours, resting, motor activity, frequency of defecation and urination, etc. in studies on meat cattle.

Grandin (2001) and Stoycheva (2014) emphasize that modern stockbreeding, respectively cattle breeding, obligatory involves a competent use of knowledge of animal behaviour and a ban on the use of physical force.

Kudrin et al. (2016) points out that a deficiency of many ethological studies is the lack of uniform criteria for assessing animal behaviour. It is almost impossible to compare data, as in most cases they are descriptive.

Sheveleva and Baharev (2003) assume that behavioural responses serve as important criteria for assessing the human-made technological conditions for animals as processes of optimal feeding, raising and realization.

The objective of the present study is to investigate the main elements of the behaviour of two groups of lactating beef cows of 'Hornless Hereford' breed, raised on a foothill, natural pasture, together with their calves.

Material and Methods

The study was carried out in the autumn of 2018 at Research Institute of Mountain Stockbreeding and Agriculture (RIMSA) in Troyan, Bulgaria on a naturally grassed pasture, situated at 386 m above sea level on a flat terrain.

The available grassland found on the pastureland was: tall fescue (*Festuca arundinacea Schreb*) 33%, Kenthucky bluegrass (*Poa pratensis* L.) 12%, quack grass (*Agropyrum repens* L.) 15%, white clover (*Trifolium repens* L.) 10%, red clover (*Trifolium pretense* L.) 5%, sainfoins (*Onobrychis viciifolia Scop.)* 5%, bird's-foot-trefoil (*Lotus cirniculatus* L.) 5%, broadleaf plantain (*Plantago mayor* L.) 3% and weeds, such as thistle (*Cardunns spp.* L.), Bermuda grass (*Cinodon dactylon* L.), greater burdock (Arctium lappaL.), wild carrot (*Dancus carota* L.) 5% etc.

Meteorological data were taken from meteorological station. Data were taken from recordings twice a day (7.00 a.m. and 9.00 p.m.) of t˚ (dry and wet thermometer), relative air humidity, wind speed, cloudiness, and precipitation.

The pasture area was about 1.5 ha and was used by 10 pure-bred 'Hornless Hereford' cows from 29.05.2018 to 30.05.2018 inclusive. The cows were conditionally divided into two groups (1^{st}) and (2^{nd} control), of 5 animals by means of electric fencing. Water intake took place in a trough mounted on the grassland itself.

The animals were on the pasture for twenty-four hours for 2 days. The behaviour of cows and calves was observed from 7.00 a.m. to 7.00 p.m. during the day and from 7.00 p.m. to 6.30 a.m. at night. Cows were identified with numbers from 1 to 10 using a colour spray. The same identification was applied to calves. There were five main behavioural reactions – grazing, having a rest (lying, standing, ruminating), moving, water intake and nursering in cows, and one major behavioural reaction in calves as suckling. The acts of aggression to humans were further investigated. Observation of the animals over the course of two days gave us the opportunity to get information on the rhythm of the behavioural reactions. Their registration was recorded in protocols for every twenty-four-hour.

The ethologological responses were determined by chronometry of the various acts by Methods of Velikzhanin et al. (1975) and Velikzhanin (2000).

We have also determined the index of motor activity (IMA), the index of feeding activity (INA) and the index of total activity (ITA) according to the following formulas:

IMA = time spend for standing + time spend in ruminating and lying/1440

IFA = time spend in grazing + time spend in ruminating/1440

ITA = time the animal spend in activity/1440

The obtained data was biometrically processed and presented in diagrams and tables.

Results and Discussion

'Hornless Hereford' was introduced to Bulgaria in the mid-1980s in the town of Troyan. The breed has been acclimatized and raised and breeds in a number of countries around the world, including Bulgaria. It is relatively unpretentious to the conditions of raising and feeding.

In the study of behavioural reactions, the impact of the climate conditions of the studied area is of interest. Air temperature and humidity are key elements of the climate, and together with the other studied components, their values are shown in Figure 1 and Figure 2.

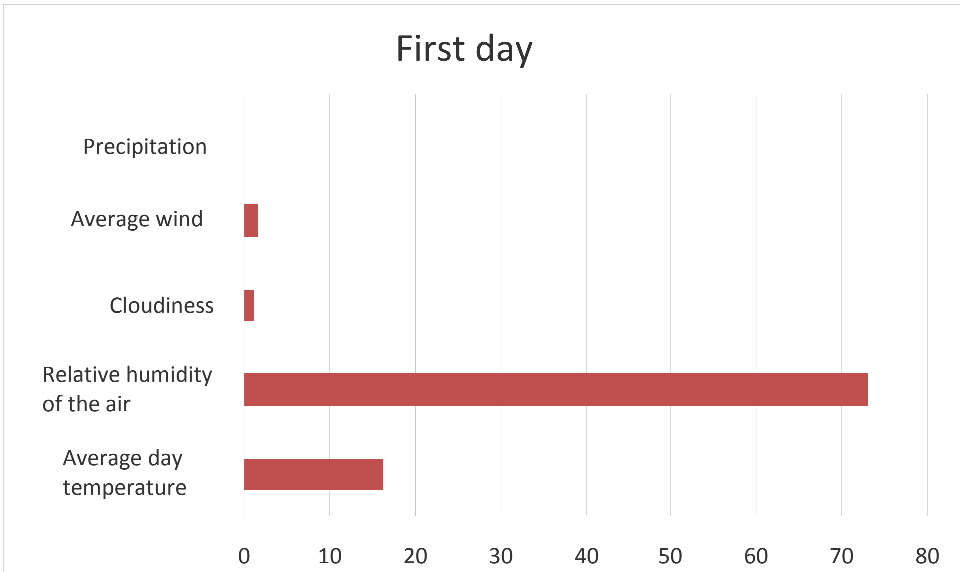

Figure 1. Components of climate and their values (1st day).

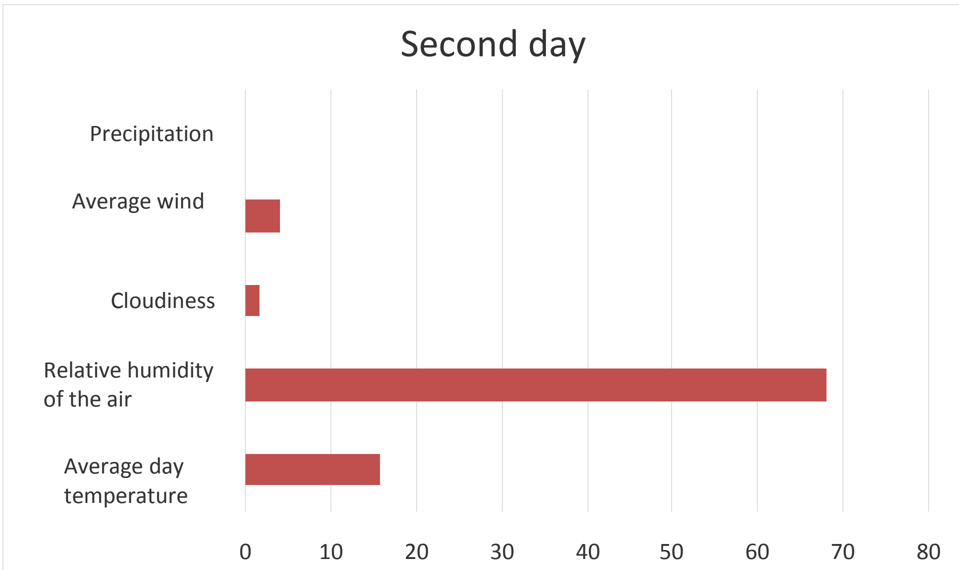

Figure 2. Components of climate and their values (2nd day).

The presented climatogram shows the average air temperature on the first day measured on a dry and wet thermometer 16.2 ° C (max. 25 °C and min. 17.5 °C). Average temperature amplitude was observed. The relative humidity is 73%, the cloudiness is 1.3 at maximum 100 and the average wind is 1.7 m/s (slight breeze), no precipitation. The weather is calm and the soil slightly damp. On the second day, the average t˚ is 15.8 °C (25 °C and minus 9 °C). Again there is average temperature amplitude. The relative humidity is 68%, the cloudiness is 1.7 at maximum 100, the average wind is 4 m/s and precipitation is 1.3 l/m². The weather is calm, the soil slightly damp. Reported temperatures are lower than the first day, the average t˚ is 0.2 ˚C less, the maximum t˚ is 25 ˚C, and the minimum t˚ shows higher values by 1.5 ˚C. No precipitation is observed. Air humidity is lower by 5%. The soil is slightly damp.
The values of the observed behavioural responses of lactating cows of 'Hornless Hereford' are shown in Table 1.

Table 1. Distribution of time for different behavioural responses in lactating cows of 'Hornless Hereford'.

Elements of behaviour	Lactating beef cattle 'Hornless Hereford' breed			
	1st group n=5		2nd group (control) n=5	
	min	%	min	%
Grazing	321.6±1.37*	22.4	330.6±1.45*	23
Having a rest: including	862.2±1.21	59.9	844.3±1.77	58.6
standing	261.4±2.86	18.2	277.4±2.44	19.3
lying	600.8±1.24	41.7	566.9±1.06	39.3
ruminating	322.6±1.17	22.4	328.1±1.25	22.8
moving	91.3±0.94*	6.3	95.4±1.04	6.6
water intake	23.5±0.04*	1.6	24.1±0.06*	1.7
nursering of calves	141.4± 1.14	9.8	145.7±1.19	10.1
Total	1440	100	1440	100

*P≤0.05

The cows of both groups observed were grazing 5.36 hours (321.6 minutes) and 5.51 hours (330.6 minutes) average per day (P≤0.05). The distance during grazing between the observed animals varied between 2.5-4 m, as the animals were in groups of 2 or 3. It is assumed that the grazing period is related to specific weather conditions. The difference between both groups (main and control) is observed during the period of rest, generally, which is 17.09 minutes or 1.3%. It is mainly attributed to the acts of standing, the difference is 1.1% as the difference for lying is 2.4%. In our opinion, this is due to the fact that different sections of the pasture were used by both studied groups at a relatively different time of day. The period for the rest was carried out on two sections of the pasture, mostly at its periphery during the day and at its center during the night. The cows were lying in a moon-like shape, with the calves in the center next to them. The value of period for rest was 862.2 minutes for the 1st group and 844.3 minutes for the 2nd group, or about 60% for twenty-four hours, as 45% of it was done during the day. The other behavioural reactions, such as ruminating, free movement and water intake are relatively close in values. During the nursing of calves the cows were standing and ruminating. Four of the mothers allowed calves of other cows to suckle from them for several times a day. There was also an aggression reaction to the people of two cows of 'Hornless Hereford', mostly in the dark of the day.

During the two periods of twenty-four hours, the calves suckled 4 to 6 times a day, and 1-2 times a night, as they were grazing or lying periodically at a distance of 2.5-4 m from their mothers.

Our data correspond and are similar in the results with the etchological studies of Novitski (1981) and Sheveleva and Baharev (2003).

Table 2. Indices for quantitative estimation of behaviour determined according to the formulas of Velikzhanin (2000).

Breed	Indices		
	IMA	IFA	ITA
Hornless Hereford (1st group)	0.823	0.447	0.625
Hornless Hereford (2nd group control)	0.814	0.457	0.641

The coefficients involved in creating the indexes used are expressed with specific values. The analysis of data from the calculated indices gives us a quantitative assessment of behaviour and shows that the index of motor activity (IMA) has high values for both groups tested, for

the first group is 0.823, and for the second one is 0.814, with a difference of 9 points in favour of the 1st group. The index of feeding activity (IFA) for the 1st group is 0.447, and for the 2nd group (control) is 0.457, or a difference of 10 points in favour of the 2nd group. For the index of total activity (ITA) the values are 0.625 for cows of the 1st group and 0.641 for the 2nd group (control), a difference of 16 points in favour of the 2nd group.
The two groups studied show lower values for the two main indices (IMA) and (IFA) that put the investigated animals in "Hyper passive" class. The decrease in the index of total activity is associated with a reduction in metabolic processes in the body and is explained by the climate, season, the productivity of the pasture used and the meteorological situation during the survey.
Our studies are similar to the results obtained in the studies of Kudrin et al. (2016) on lactating Ayrshire cows.

Conclusions

The physiological state, the elements of the climate, alimentary conditions and the system of raising have an impact on the behavioural reactions of lactating beef cows. The data obtained suggest that animals from 'Hornless Hereford' have good adaptive abilities for pasture farming in late spring in the conditions of the town of Troyan, the Republic of Bulgaria, a foot-hill terrain at 386 meters above the sea level of a natural pasture with predominant grassland of grasses and legumes and motley grasses with weeds. The time spent in grazing is comparable to that recorded under other climatic conditions, pasture composition and breeding of beef cattle. The animals of both groups tested were characterized by imitating behaviour, especially in grazing, resting and suckling of calves. Joint grazing with the mother is an important element in teaching of calf to graze. Lactating cows showed a good maternal instinct, as four of them allowed suckling of calves of other cows. Two of the lactating cows showed an aggressive behaviour in the form of attack when people approached.

Abstract

This experiment was designed to study the effect of drinking saline water on growth performance, water intake and blood parameters in local sheep reared under Tunisia conditions. Twenty of Barbarine lambs (initial body weight 23.5±4.5 kg). The lambs were divided into two homogenous groups regarding age and live weight. Animals are grazed in the open rangeland area of vetch. Control group had free access to a normal water, while the second group received water enriched with 10 g NaCl/l. The obtained results indicated that water intake, body weight, live body gain daily, plasma glucose and gamma glutamyl transferase were not affected by increasing salt concentration in drinking water. However, plasma cholesterol, total protein, albumin, creatinine, urea triglyceride, were significantly affected ($p<0.05$&0.01) by salinity. Barbarine local sheep could tolerate the salinity of water

Keywords: *sheep, salinity, intake, blood and rumen metabolism.*

Introduction

Sheep are considered one of the most important grazing animals that can affect the social and economic status of people inhabiting arid and semi-arid regions. Water is an essential nutrient; therefore, it is important for animals to have an adequate supply of good quality water to survive and maintain satisfactory production (Schoeman and Visser, 1995). Around 50% of all water resources have salinity levels below 1.5 g/l, thus could be used for human consumption and above 1.5 g/l. Shetty (2004) estimated that 30% of the shallow aquifers have a salinity level above 4 g/l.

In practice, it is difficult to quantify the amount of salt intake. Animals may consume halophytes and/or drink saline water of various salinity levels.

However, the available findings on the effect of water salinity on growth rate and blood parameters of sheep are limited.

In Tunisia, particularly in the arid and semiarid regions, groundwater salinity is increasing and it is currently in the range of 3000 to12000 ppm TDS. To the best of our knowledge, the response of grazing sheep to the high salinity level is not documented. Therefore, the present experiment aimed to determine the effect of drinking saline water on growth rate and blood metabolites of Barbarine lamb grazing vetch without any supplement.

Materials and methods

Animals and management

This experiment was carried out from June to September 2013 at the experimental station of the National Institute of Agricultural Research of Tunisia (INRAT) at Bourbia (25 km south of Tunis. The average temperature during this spring period is 36°C. Twenty male barbarine sheep were used to determine the effect of saline drinking water on growth performances, water intake and blood parameters. Animals were weighed and divided into four groups on basis of body weight. Animals in each group grazed the common vetch (a local variety). They

were 2 weeks of adaptation. Animals were treated for internal parasites prior to commencement of the experiment.
The experimental groups were:
Group 1 (NW) (grazing + drinking fresh water)
Group 2 (NW) (grazing + drinking water + 10g salt).

The chemical compositions of water are shown in Table 1.
Table 1. Chemical composition of the water utilized during the trial.

Item	*Water*	
	Control	*NaCl enriched*
Dry residue (g/l)	1.08	11.24
pH	7.01	6.90
Sodium (mg/l)	200	3700
Potasium (mg/l)	5	12
Calcium (mg/l)	85	230
Magnesium (mg/l)	34	26
Chlorures (mg/l)	350	6568
Sulfates (mg/l)	230	144
Carbonates (mg/l)	0	0
Bicarbonates (mg/l)	6	6
S.A.R	4.62	61.54
D°H	35	68

Water intake, body weight, weight gain and blood parameters

The animals were grazed in the morning (from 06:00 to 09:00h) and afternoon (from 15h to 16h) and then moved back to the individual barn to receive the normal water (NW) or salt water (SW).
A sample of vetch, at the start and end of the feeding period, were analysed for dry matter (DM,), ash and N (Kjeldahl-N) according to AOAC (1990). The procedure described by Van Soest et al. (1991) using the ANKOM220 system was used to analyse neutral detergent fibre (NDF). Acid detergent fibre (ADF) of feeds was determined and expressed exclusive of residual ash (AOAC, 1990). Lignin of feeds was analysed by solubilisation of cellulose with 720 g/kg sulphuric acid (Robertson and Van Soest, 1981). The contents of NDF, ADF and lignin were expressed as ash-free.
During the experimental period, the average of the morning and evening drinking was taken as a daily water intake. Animals were weighed every two weeks fasting to monitor body weight changes.
Blood samples, before the morning feeding, were obtained via Jugular vein puncture using Heparin as the anticoagulant and were then centrifuged at 3000×g at 4◦C. The plasma was separated, and samples stored at -20°C for the subsequent spectrophotometric analysis of the cholesterol, total protein, albumin, creatinine, urea triglyceride, gamma glutamyl transferase contents using the Biomaghreb laboratory kits

Statistical analysis

Data on body weight, blood parameters and water intakes were subjected to the analysis of variance the mixed model with repeated measurements (SAS, 1991). The model included effects of watering regimens, period, and their interaction. Means were compared by the least significant difference (LSD) and significant difference between treatment effects was considered when P-value is below 0.05.

Results and discussions

Composition of diets and water

The chemical compositions of vetch are shown in Table 2.

Table 2. The chemical composition of vetch (%, DM basis)

	Start of the feeding period	End of the feeding period
Dry matter	90.34	91.98
Organic matter	93.25	84.68
Crude protein	16.2	5.4
Neutral detergent fiber	62.44	65.23
Acid detergent fiber	39.03	52.64

DM, dry matter;

The results of this analysis show that the vetch is low in CP at the end of feeding period (5.4%) and rich in NDF and ADF (65.23% and 52.64 %).

Effect of salinity water on water intake

Water intake is influenced by several factors; of which is the water quality (salinity). Species adapted to arid and semi-arid areas may consume more water than others (Wilson, 1989). The data represented in table 3 showed the effect of water on water intake. Animals responded to increasing salinity level in drinking water by increasing water intakes. However, water intake was not affected by the treatment (P>0.05). These results agree with those reported by Wilson and Dudzinki, (1973), Gihad and *al.* (1993) and Attia-Ismail and *al.* (2008).

Table 3. Effect of water salinity on water intake.

Item	*Diet*		*SEM*	*P- value*
	NW	*SW*		
Liter/day	5.01	5.06	0.120	0.789
Liter/kg $BW^{0.75}$	0.365	0.377	0.017	0.612
Liter/kg OMI	14.63	18.20	5.015	0.633

OMI, organic matter intake; NW, water normal; SW, water salinity; BW, body weight; SEM = Standard error of mean

Effect of salinity water on growth rate

The data represented in Table 4 showed the effect of drinking saline water on body weight. These data indicated that, initial body weights, final body weights and average daily gain of lambs remained unaffected by salinity (P>0.05). The results agree with those reported by Said Shannan et *al.* (2010).

Table 4. Effect of salinity water on body weight.

Item	*Treatments*		*ESM*	*P*- value
	NW	*SW*		
Initial body weight (kg)	23.60	23.45	1.480	0.942
Final body weight (kg)	33.49	32.24	1.588	0.585
Average daily gain (g)	152.07	147.53	6.798	0.642

NW, water normal; SW, water salinity; SEM = Standard Error of Means

Effect of salinity water on blood parameters

Plasma metabolites are presented in Table 5. The concentrations of glucose and gamma glutamyl transferase were not influenced by the water salinity (P>0.05). Assad and El-Sherif (2002) reported similar findings. However, plasma cholesterol, total protein, albumin, creatinine, urea and triglyceride were significantly affected (P<0.05& 0.01) by salinity. This result may relate to dilute out the retained salt by the fact that water is held to the body fluids (Tietz, 1982; Ayyat and *al.*, 1991; Suckow and Douglas, 1997).

Table 5 Effect of salinity water on blood parameters

Item	*Period, treatments*					*P- value*		
	1		*2*					
	NW	*SW*	*NW*	*SW*	*ES*	*Period*	*Diet*	*Interaction*
Albumine (mg/l)	55.03	90.90	58.91	87.53	4.004	0.950	<0.001	0.372
Creatinine (mg/dl)	0.90	1.26	0.88	1.33	0.031	0.478	<0.001	0.109
Cholesterol (mg/dl)	47.00	69.94	61.08	71.87	4.042	0.463	0.005	0.792
Triglyceride (mg/dl)	17.60	15.29	21.05	17.46	0.551	<0.001	<0.001	0.255
Urea (mg/dl)	36.02	50.75	39.66	54.01	1.323	0.013	<0.001	0.886
Total protein (g/l)	88.05	72.20	98.78	80.90	2.817	0.001	<0.001	0.721
Glucose (mg/dl)	49.12	47.70	54.90	51.74	1.810	0.010	0.215	0.637
ɤ-gt (U/l)	10.53	8.23	8.69	6.36	0.995	0.070	0.025	0.990

NW, water normal; SW, water salinity; SEM = Standard error of means

Conclusion

The current study revealed that the effect of saline water on water intake, growth performance and blood metabolites of Barbarine lamb can affect some parameters but cannot modify significantly other parameters. The results indicated better tolerance of Tunisian local sheep to saline load. Further study is required to determine if other breeds of local sheep can tolerate these salinity levels.

Abstract

Lactating Holstein-Friesian Black-and-White dairy cows (n=4×5) were included in the trial in the initial lactation phase with the average milk yield of 30.00 kg per day, fat content 4.10% and 3.20% protein content in milk. The analyses of the chemical content of beans and peas showed, that crude protein and undegraded intake protein were higher in beans than in peas, respectively 29.97% and 25.04% of dry matter, undegraded intake protein content, respectively 40.51% and 39.69% of crude protein. The highest content of starch was 48.54% in peas, and 43.29% in beans, but it was the lowest in soybean meal - 7.62% of dry matter. There were 17 amino acids in total detected in beans, peas and soybean meal. The highest concentration of arginine, leucine, glutamic acid, aspartic acid and isoleucine was in beans - 0.76%, 0.58%, 0.67%, 0.42% and 0.29%, respectively which was more than in peas. Even though the daily milk yields decreased for all the cow groups during the experiment, which was normal during the lactation period, yet the milk yield decreased for the trial groups. The milk yield decreased for the trial groups (1st and 2nd) were smaller – 0.8 kg, 1.3 kg, respectively, compared with the initial stage of the experiment ($P< 0.05$). In contrast, group 4 showed a significant decrease in the average daily energy corrected milk yield (4.9 kg), compared with the initial stage of the trial. Compared with the control group, none of the dietary interventions showed significant ($P>0.05$) deviations. The highest total amount of amino acids in milk was detected in 3rd and 2nd trial cow groups, fed with fodder beans and peas respectively, 4.00 g/kg and 3.90 g/kg, respectively.

Keywords: *beans and peas, amino acids, dairy cows, milk.*

Introduction

Sustainable feed production and feeding are key factors in achieving resource-efficient and resilient livestock production systems with minimal environmental load and high product quality *Faba* bean is a protein-rich legume seed well adapted to most climatic areas of Europe and widely used for feed. A sustainable animal diet is characterized as a diet that is balanced in all nutrients and free from harmful components, meets production objectives, generates animal products safe for human consumption, and integrates the planet, people, profit, and ethical dimensions of sustainability. Among the possible alternatives, the *faba* beans and peas appears interesting for dairy cow diet (Makkar, 2016; Makkar and Ankers, 2014; Crépon, Pascal, Peyronnet, *et al*., 2010). The common reason for livestock producers to plant *faba* beans is to obtain a protein source that is home grown and that can easily be processed on-farm, as they contain little oil. They also do not contain anti-nutritional enzymes and therefore do not need roasting. Faba beans are related to lima beans and contain approximately 30% protein (Volpelli *et al*., 2010; Heeg, 2016). Field peas are highly digestible and highly fermentable in the rumen, but have a slower starch and protein fermentation rate than several other common feeds. Therefore, fodder beans and peas be used as an important forage legume to enhance feed values for dairy ruminants, especially of importance to today's high yielding dairy cows (Jensen, 2002; Ipharraguerre and Clark, 2005). The European Union policy on the protection and enhancement of biodiversity on agricultural holdings has contributed to an increase in the area sown with legumes in Latvia.

The objective of the present paper is to investigate the beans and peas in the diet of dairy cows' feed.

Material and Methods

Trials were carried out in the farm "Upites", Allazu Parish, Allazmuiza Municipality during the winter period from December to February (Latvia). For the trial, four analogue (according to yield, lactation phase, live weight, fat content and protein content) treatments groups of 20 animals of Holstein-Friesian Black-and-White cows were used in the study. Feeding trial was carried out 90 days. The experimental design is reported in Table 1.

Table 1. Scheme of the trial.

Group of cows	Number of cows	Feeding programme
1st trial	5	Basic feed + 10-12% *Pisum sativum*'Bruno' + 10 - 12 % *Vicia faba minora*'Lielplatone'
2nd trial	5	Basic feed + 20-24% *Pisum sativum*'Bruno'
3rdtrial	5	Basic feed + 20-24% *Vicia faba minora* 'Lielplatone'
4th control	5	Basic feed with soybean cake

The average live weight of cows in all groups were 650 kg the mean age was 3.0 lactations. The cows were in the initial phase of lactation were included in the experiment with the average yield of 30.00 kg per day, fat content 4.10% and protein content 3.20%. The cows are kept on the same farm, under equal feeding, housing and exploitation condition. During the trial, the dairy cows received the basic feeding ration (Table 2).

Table 2. Dairy cows feeding during the trials.

Feedstuffs	Amount, kg	1st trial	2nd trial	3rd trial	4th control
Silage	40	40	40	40	40
Hay	3	3	3	3	3
Concentrated feed	4	4	4	4	4
Complementary feed	4	4	4	4	4
Peas plus beans	-	1.82	-	-	-
Peas	-	-	1.9	-	-
Beans	-	-	-	1.7	-
Soybean meals	-	-	-	-	1
Mineral additive	0.15	0.15	0.15	0.15	0.15
Feed ration contains:					
Dry matter, kg	-	21.60	21.70	21.50	20.80
Crude protein, g	-	3266	3261	3276	3258
NEL, MJ	-	142.7	143.8	139	137.20
Calcium, g	-	153	157	155	162
Phosphorus, g	-	82.0	83.0	85.0	82.0

The feeding ration varied according to each cows' milk yield and physiological state, and was corrected monthly depending on the results of control milk yield, dry period and state of health. When elaborating the feeding rations, we took into consideration the following: amount of feedstuffs, dry matter (DM), net energy for lactation (NEL, MJ), amount of crude protein, calcium and phosphorus (Nutrient Requirements…, 2001).

A full value chemical analyses were conducted by the accredited Scientific Laboratory of Biotechnology, Department of Agronomic analyses of the Agronomical Analyses under the Latvia University of Life Sciences and Technologies. The biometric data were analysed by a Mann-Whitney test at the significance level $\alpha = 0.05$ to identify differences in comparison with the control group (Montgomery, 2012). All statistical analyses were performed using SPSS for Windows version 20.0.

Results and Discussion

The chemical composition of fodder beans, peas and soybean meal are presented in Table 3. As can be seen from data, the content of dry matter in peas (*Pisum sativum*) "Bruno" and fodder beans (*Vicia faba minor*) "Lielplatone" was high, 90.78% and 90.44% respectively but in soybean meal - 87.41%. Crude protein content was the highest in soybean meal - 50.61% and beans - 29.97%, while in peas - 25.04% of dry matter. Soybean meal had significantly high content of UIP - 73.99% of crude protein.

After summarizing reference data, undegraded intake protein (UIP) content in soybean meal in the rumen fluctuates within the range of 75 to 78 per cent (Singh *et al*., 2012). Relatively high percentage of UIP was also in fodder beans - 40.51%, whereas in peas it was 39.69% of the crude protein. According to Batterham and Egan (1986), the amount of UIP can make up 46% of crude protein content.

Table 3. The chemical composition, on dry matter basis, %.

Indices	Beans "Lielplatone"	Peas "Bruno"	Soybean meal
Dry matter, %	90.44	90.78	87.41
Crude protein, %	29.97	25.04	50.61
UIP of crude protein, %	40.51	39.69	73.99
Crude fat, %	1.09	1.22	1.60
Starch, %	43.29	48.54	7.62
Crude fiber, %	9.5	7.21	3.57
NDF, %	15.79	20.58	13.98
ADF, %	11.36	9.59	6.91
NEL, MJ kg^{-1}	7.7	7.84	7.89
Crude ash, %	3.61	3.28	1.76
Ca, %	0.12	0.07	0.42
P, %	0.66	0.43	0.71
Digestibility, %	80.00	81.40	81.80

The highest concentration of arginine, leucine, glutamic acid, aspartic acid and isoleucine was in fodder beans, respectively 0.76%, 0.58%, 0.67%, 0.42% and 0.29% of dry matter more than in peas (Table 4). Methionine, cystine, lysine, threonine, histidine, phenylalanine, tyrozine, glycine, serine and alanine amount in beans and peas was similar. The highest concentration of amino acids was shown soybean meal.

Table 4. The amino acids content, on dry matter basis, %.

Amino acids	Beans "Lielplatone"	Peas "Bruno"	Soybean meal
Methionine	0.21	0.22	0.61
Cystine	0.33	0.30	0.68
Lysine	1.71	1.50	2.80

Threonine	0.97	0.77	1.82
Arginine	2.54	1.78	3.35
Isoleucine	1.14	0.85	2.10
Leucine	2.05	1.47	3.45
Valine	1.21	0.95	2.21
Histidine	0.69	0.50	1.20
Phenylalanine	1.14	1.04	2.32
Tyrosine	0.84	0.64	1.63
Glycine	1.17	0.90	2.00
Serine	1.22	1.01	2.37
Proline	-	0.77	-
Alanine	1.10	0.92	2.06
Aspartic acid	2.82	2.40	5.27
Glutamic acid	4.42	3.75	8.29

However, compared to cereals, the content of lysine in beans is relatively high and the contents of the sulphur-containing amino acids cysteine and methionine are low. According to reference materials, beans mainly contain lysine, with minor concentrations of methionine and tryptophan (Crepon et al., 2010).
The greatest decrease in cow productivity (Table 5) was observed for the control group – by 3.98 kg of milk but a smaller decrease was observed for the 3 rd group – by 0.26 kg, of milk compared with the before the trial (P < 0.05).

Table 5. Cow productivity during the trials, on average, kg.

Group of cows	Before the trial	Beginning of the trial	Middle in the trial	End of the trial	Comparison between before and end values
1st trial	22.68	23.52	22.24	20.46	-2.22
2nd trial	23.48	21.58	21.76	21.38	-2.10
3rd trial	20.74	19.70	20.28	20.48	-0.26
4th control	24.62	24.92	21.96	20.64	-3.98
p–value (relative to control)					
Group of cows	Before the trial	Beginning of the trial	Middle in the trial	End of the trial	*P*-value (ralative to values at the before the trial)
1st trial	0.465	0.600	0.917	0.917	0.225
2nd trial	0.917	0.347	0.917	0.754	0.138
3rd trial	0.251	0.251	0.917	0.916	0.893
4th control	-	-	-	-	0.043 S

S significant differences (P < 0.05)

The content of total amount of amino acids in milk is shown in Table 6. The highest increase was found in the bulk milk samples of the 3rd and the 2nd trial group, 4.00 g/ kg and 3.90 g/ kg, respectively. The lowest increase was in the bulk milk samples of the 1st trial group 1.80 g/ kg, respectively, compared with the initial stage of the experiment. However, an increase in the total amount of amino acids was observed in the control group, respectively 2.30 g/kg. The trial group 3rd, which were fed beans, showed the amount of total amino acids in milk that was 1.70 g/kg higher than in control group that was fed soybean meal ($P<0.05$).

Table 6. The content of total amount of amino acids in milk, g/kg.

Group of cows	Before the trial	End of the trial	Comparison between initial and final values
Group of cows	30.2±0.44	32.0±0.68	+1.80
1st trial	29.2±0.49	33.1±0.71	+3.90
2nd trial	30.5±0.37	34.5±0.52	+4.00
3rdtrial	31.4±0.32	33.7±0.39	+2.30
4th control	30.2±0.44	32.0±0.68	+1.80

It is known that the cow farming technology, including cow feeding, can considerably affect milk yield. After examining the effects of different amounts of dietary legumes on productivity of dairy cows, Vander *et al*., (2008) demonstrated no significant changes when soybean flour is partially replaced by peas (150 g/kg). A similar finding was made by Tufarelli *et al*., (2012) who reported that replacing soybeans with faba beans (345 g/kg) in the diet for highly productive dairy cows (the average milk yield of 35 kg a day) did not influence the cows' productivity.

Conclusions

Obtained results of chemical composition of beans "Lielplatone", peas "Bruno" and soybean meal the content of crude protein content was the highest in soybean meal - 50.61% and beans - 29.97%, while in peas - 25.04% of dry matter. The highest content of starch was in peas - 48.54%, beans - 43.29% but the lowest in soybean meal - 7.62% of dry matter.

Upon the whole, it can be concluded that the highest rate of essential amino acids was detected in soybean meal and beans "Lielplatone", while the lowest - in peas "Bruno".

During the trial, the cow productivity indicators decreased for all the groups, which was normal during the lactation period, yet the daily milk yield decreases for the trial groups were smaller – 2.22 kg, 2.10 kg and 0.26 kg, respectively, compared with before the trial and the control group.

The highest total amount of amino acids in milk was detected in 3rd and 2nd trial cow groups, respectively, 4.00 g/kg and 3.90 g/kg, which was fed fodder beans and peas but the lowest amino acid amount was detected in trial group 1st - 1.80 g/kg, which was fed peas plus fodder beans compared with the initial stage of the trial.

Abstract

A total of 192 specimens of common carp (*Cyprinus carpio*), 38 specimens of grass carp (*Ctenopharyngodon idella*), as well as 26 specimens of bighead carp (*Hypophthalmichthys nobilis*), from the most significant and larger cyprinid aquaculture facilities in Macedonia, including fish farms and reservoirs, were examined for parasitological investigations. This study was carried out by seasons. Protozoa *Ichthyophthirius multifiliis* is the largest known parasitic protozoan found on fishes. In our study, this protozoa was found in all seasons, except in winter. Total, prevalence with *I. multifiliis* in cyprinid fishes from aquaculture facilities in Macedonia, by seasons, was as following: spring - 0.79 %; summer - 2.99 % and autumn - 0.44 %, while mean intensity was: spring - 12.56; summer - 26.70 and autumn - 50.00. The records of *I. multifiliis* in grass carp and bighead carp in the present study is considered as the first records in Macedonia. Also, these two fish species is regarded as new hosts for *I. multifiliis* in Macedonian waters.

Keywords: *protozoa, Ichthyophthirius multifiliis, common carp, grass carp, bighead carp*

Introduction

One of the largest family of freshwater fishes in the world is family Cyprinidae, with several genera, among which *Cyprinus*, *Hypophthalmichthys* and *Ctenopharyngodon* are the most significant, with representatives of common carp (*Cyprinus carpio*), bighead carp (*Hypophthalmichthys nobilis*) and grass carp (*Ctenopharyngodon idella*), respectively. These are warm water fish species which are successfully grown in aquaculture facilities in Macedonia.

Parasites are among the pathogenic factors that are very important for fish health and responsible for economic losses in the fish industry. According Blazhekovikj - Dimovska and Stojanovski (2015), parasitic diseases represent negative factor, which in intensive fish farming can cause considerable damages in aquaculture. Parasites in the waters where they are present sometimes cause fish reduction, thereby directly affecting on fish stocks in the country.

The ciliated protozoan, *Ichthyophthirius multifiliis*, the causative agent of ichthyophthiriasis or Ich, is one of the most important pathogenic parasites of cultured fish (Schäperclaus, 1991). This protozoan is widely distributed to all parts of the world and almost all of the freshwater fish are susceptible to infections. According Buchmann *et al.* (2001), the life cycle of this parasite is divided into three stages: a trophont, a tomont (which is divided into tomites) and a theront. The trophont is a parasitic stage that lives and feeds on the epidermis of the fish-host, where it can reach a diameter greater than 1 mm. A number of studies have shown that all these life cycle stages are extremely temperature dependent. The mature parasite is very large, up to 1000 μm in diameter, very dark in color due to the thick cilia covering the entire cell and moves with an amoeboid motion.

According Svobodova and Kolarova (2004), ichthyophthiriasis is one of the most serious parasitic diseases in freshwater fish which can cause large losses in fish population. The same authors noticed that high water temperatures, high stocking density, fish weakening as a result of malnutrition, are important conditional factors affecting on disease appearance. The disease appears in all facilities for intensive fish breeding.

In order to take certain preventive measures, it is necessary to know the composition of parasite fauna in economically most important fish species, their seasonal dynamics as well as prevalence and mean intensity of certain parasites in different age categories of fish in aquaculture facilities.

The aim of this study was to determine the presence of protozoan parasite *I. multifiliis*, prevalence, mean intensity, as well as, seasonal changes of parasite species in fish family Cyprinidae from the most significant and larger cyprinid aquaculture facilities in Macedonia, including fish farms and reservoirs. This study has chosen a protozoon which can impose a noticeable economic damages and losses to the fish breeding.

Material and methods

This parasitological study was carried out by seasons. A total of 192 specimens of common carp (*Cyprinus carpio*), 38 specimens of grass carp (*Ctenopharyngodon idella*), as well as 26 specimens of bighead carp (*Hypophthalmichthys nobilis*), from eight the most significant and larger cyprinid aquaculture facilities in Macedonia, including fish farms and reservoirs, were examined for parasitological investigations. These aquaculture facilities included fish farms Zhabeni, Bukri, Dolneni and Zhelezara, as well as cage culture systems on reservoirs Tikvesh, Mladost, Globochica and Gradche.

The fish were caught using net or hook by local fishermen. The specimens were placed in plastic tanks with ice and transferred to the research laboratory. The work on specimens was achieved immediately. Fish were killed by vertebral dislocation. The gill filaments, the eyes, the fins, the skin and the intestine of fishes were inspected by stereomicroscope and in second phase direct smears were prepared from probable lesions.

All parasites found in each individual fish were identified and enumerated. Preparation, fixing, staining and mounting of parasites were made by general methods used in parasitology. During the study period, data on parasite species were categorized according to season. Classical epidemiological variables (prevalence and mean intensity) were calculated according to Bush *et al.* (1997). The parasite specimens were identified according reference keys of Bykhovskaya-Pavlovskaya *et al.* (1962) and Gussev (1983).

During the examinations at Laboratory for fish diseases in Hydro - biological Institute in Ohrid (Macedonia), stereomicroscopes „Zeiss"- Stemi DV4 and „MBS 10", as well as light microscope „Reichart" were used.

The number of fish examined, fish infected, prevalence and mean intensity (total and by seasons) are given in tables.

Result and discussion

A total of 256 specimens of fish family Cyprinidae (192 specimens of common carp, 38 specimens of grass carp, as well as 26 specimens of bighead carp) from eight the most significant and larger cyprinid aquaculture facilities in Macedonia, including fish farms and reservoirs, were examined for parasitological investigations and 53 fish (20.70 %) were infected with protozoan parasite *Ichthyophthirius multifiliis*. This parasitological study was carried out by seasons.

Protozoa *I. multifiliis* is the largest known parasitic protozoan found on fishes. In our study, it was found in 53 specimens of fish family Cyprinidae, from two cyprinid aquaculture facilities:

1. On fins and gills in 34 specimens of common carp (*Cyprinus carpio*) from cage culture system on reservoir Globochica, in summer season. The prevalence with *I. multifiliis* in

common carp was 3.55 %, while the mean intensity was 26.70.
2. On fins and gills in 14 specimens of grass carp (*Ctenopharyngodon idella*) from fish farm Zhabeni, in spring season. The prevalence with *I. multifiliis* in grass carp was 18.42 %, while the mean intensity was 25.93.
3. On gills in 5 specimens of bighead carp (*Hypophthalmichthys nobilis*) from fish farm Zhabeni, in autumn season. The prevalence with *I. multifiliis* in bighead carp was 9.43 %, while the mean intensity was 50.00.
In our study, this protozoan was found in all seasons, except in winter. Total, the prevalence with *I. multifiliis* in cyprinid fishes from aquaculture facilities in Macedonia, by seasons, was as following: spring - 0.79 %; summer - 2.99 % and autumn - 0.44 %, while the mean intensity was: spring - 12.56; summer - 26.70 and autumn - 50.00.
The records of *I. multifiliis* in grass carp (*Ctenopharyngodon idella*) and bighead carp (*Hypophthalmichthys nobilis*) in the present study is considered as the first records in Macedonia. These two fish species is regarded as new hosts for *I. multifiliis* in Macedonian waters. Also, this is first finding of *I. multifiliis* in common carp from cage culture system on reservoir Globochica.
Data on fish examined, fish infected, as well as the prevalence and mean intensity with *I. multifiliis* (total and by seasons) are given in Table 1 and Table 2.

Table 1. Number of examined and infected fish, percent of infestation, total prevalence (E) and mean intensity (I) with protozoan parasite *Ichthyophthirius multifiliis*

Fish species	Number of fish examined	Number of fish infected	Percent of infestation	Total	
				I	E (%)
Common carp ***(Cyprinus carpio)***	192	34	17.70 %	26.48	4.23
Grass carp ***(Ctenopharyngodon idella)***	38	14	36.84 %		
Bighead carp ***(Hypophthalmichthys nobilis)***	26	5	19.23 %		

Table 2. Prevalence (E) and mean intensity (I) with protozoan parasite *Ichthyophthirius multifiliis* in fish family Cyprinidae from aquaculture facilities in Macedonia, by seasons

Fish species	Spring		Summer		Autumn		Winter	
	I	E (%)	I	E (%)	I	E (%)	I	E (%)
Common carp ***(Cyprinus carpio)***	/	/	26.70	3.55	/	/	/	/
Grass carp ***(Ctenopharyngodon idella)***	25.93	18.42	/	/	/	/	/	/
Bighead carp ***(Hypophthalmichthys nobilis)***	/	/	/	/	50.00	9.43	/	/

During this study, infection with *I. multifiliis* was recorded on fish in all seasons with exception of winter (Table 2). Mean intensity of *I. multifiliis* was not varied among the spring and summer seasons, but it was significantly higher in autumn season. The greatest value of mean intensity was recorded in autumn (50.00) in bighead carp.
Prevalence (%) of *I. multifiliis* was the highest in spring (18.42) and lowest in summer (3.55) (Table 2).
I. multifiliis is a single cell infusoria size of 0.2 - 1 mm. It has a round or an egg shape, with thick cilia on the surface of the body, which uses for moving and attaching to the fish body. In

the middle of the body it is a fat macronucleus that has a crescent shape. This parasite is visible with eye.

Fig. 1. *Ichthyophthirius multifiliis* (original)

Moreover, in our study, we were unable to detect any trophont of *I. multifiliis* in the winter season, in all three fish species. Frequent ichthyophthiriasis epizootics at higher water temperature (24– 26ºC) were also reported from the farms of North America (Wood, 1979) and Europe (Valtonen and Keräen, 1981).
According to the present results, the prevalence and mean intensity of *I. multifiliis* in grass carp was 18.42 % and 25.93, respectively, and it is relatively high. However, different prevalence and mean intensity in various fish species has been reported in previous literatures (Kuperman *et al.,* 2002). Therefore, the diversity of hosts of this parasite and various prevalence and mean intensities are probably related to the different possible influences of environmental and nutritional factors.
Moreover, temperature changes have main effect on each stage of development e.g. encystment, division and maturity of *I. multifiliis* (Aihua and Buchmann, 2001). Fish species with high prevalence probably are living in a favorable temperature for parasite, because considerable changes in temperature will kill these ciliates (Nigrelli *et al.,* 1976). Buchmann and Bresciani (1997) demonstrated that *I. multifiliis* in traditional fish farms was more prevalent at high temperatures. Moreover, our study clearly shows that the development of *I. mulifiliis* was inhibited at lower temperatures and increased at higher temperatures.
The external parasites of fish were previously investigated in Macedonia. To date, *I. multifiliis* have been recorded in fish from Macedonian waters. According to the data from the previous parasitological research in Macedonia, Hristovski *et al.* (1999, 2001) have established the *I. multifiliis* of skin and gills in common carp from the fish farm Zhabeni. This parasite has been determined by Hristovski *et al.* (2006, 2012) in other fish species from Prespa Lake, including *Rutilus rubilio prespensis, Barbus cyclolepis prespensis* and *Leuciscus cephalus albus*. According to the literature data from the surrounding countries, findings on the presence of *I. multifiliis* in common carp and grass carp in Bosnia and Herzegovina were first published by Žitnan *et al.* (1969) in the fish farm "Vuchijak" – Prnjavor, in waters in Serbia by Cakić

(1992), while in Croatia this parasite was established at the fish population in the Krka River, by Valić *et al.* (2005).
Data on the presence of *I. multifiliis* on the gills, in the body and nasal cavity of common carp from fish farms in Romania, were published by Radu *et al.* (2008); in two-year-old carps from fish farms in the Czech Republic, by Ondračková *et al.* (2012); while Szekely & Molnar (1996 - 1997) established this parasite in common carp from Lake Balaton, Hungary. According to literature data from the world, the presence of *I. multifiliis* in common carp was determined by Cengizler *et al.* (2001) in the river Seyhan, Turkey; Raissy *et al.* (2010) and Bozorgnia *et al.* (2012) in fish farms in Iran; Ali *et al.* (1988), Al-Marjan and Shamall (2008) and Mansoor and Al-Shaikh (2010) in fish farms in Iraq and Subasinghe (1992) in fish farms in Sri Lanka.
According Abowei *et al.* (2011), the severe infestations with this parasite in fish result in anxiety, atrophy, body irritation and asphyxia. Morbidity can be 100%, while mortality occurs only in significant damage to the gills and skin. According Sao Clemente *et al.* (2000), in the more advanced stages of the disease, the fish become lethargic, stop consuming food and die from asphyxia.
Sao Clemente *et al.* (2000) and Dickerson (2006) considered that the *I. multifiliis* has a wide distribution and parasites in many freshwater fish in all stages of development, ranging from offspring to adult fishes, which is correlated with the results of our research.

Conclusions

Ichthyophthirius multifilis is an epizootiologically important parasite in all economically significant fish species that are grown in cyprinid aquaculture facilities, attacking the skin, gills and fins of the fish. Ichthyophthiriasis (Ich) or "white spot disease" is one of the most serious diseases of fishes and as a devastating pathogen in aquaculture, is responsible for substantial economic losses worldwide.
In our study, total, the prevalence with *I. multifiliis* in cyprinid fishes from aquaculture facilities in Macedonia, by seasons, was as following: spring - 0.79 %; summer - 2.99 % and autumn - 0.44 %, while mean intensity was: spring - 12.56; summer - 26.70 and autumn - 50.00. This protozoan was not found in winter.
The prevalence with *I. multifiliis* in common carp, grass carp and bighead carp was 3.55 %, 18.42 % and 9.43 %, respectively, while the mean intensity was 26.70, 25.93 and 50.00, respectively.
The records of *I. multifiliis* in grass carp (*Ctenopharyngodon idella*) and bighead carp (*Hypophthalmichthys nobilis*) in the present study is considered as the first records in Macedonia. These two fish species is regarded as new hosts for *I. multifiliis* in Macedonian waters.
Also, this is first finding of *I. multifiliis* in common carp from cage culture system on reservoir Globochica.
Since these parasites are dangerous and cause a strong negative impact on fish population, it is necessary to identify such parasites and take control measures, especially for important fish species such as common carp, bighead carp and grass carp.

Abstract

The influence of the feeding of forager bees with the pollen of different quality on the size of the hypopharyngeal glands was studied in this paper. Forager bees, 1-2 days old, were sampled from the frames with an emerging brood and were kept in mini cages where they were fed with different types of pollen. Pollen was collected during the pollination of the red clover, and it was classified by color in 4 categories: beige, yellow, orange and gray. The beige pollen was from red clover while other colors were not identified. Pollen quality was determined by standard chemical methods, and the following parameters were studied: ash, crude protein, fats, cellulose, macro-elements (P, K) and certain micro-elements (Ca, Mg, Fe, Zn and Mn). The gray pollen had the highest ash and crude protein, while the beige one had the most crude fats and cellulose. Pollen was added into the sugar dough (cake). The control treatment was without pollen, and only the sugar dough was used. The largest glands have developed in the group of bees fed with the beige pollen (8.17 µm), and the smallest glands were found in bees fed only by sugar dough (the control, 6.53 µm) and with the gray pollen (6.84 µm), although it had the most protein. The differences between treatments were statistically significant. Three homogeneous groups were distinguished, and bees fed with red clover pollen were very different from other studied groups.

Key words: hypopharyngeal glands, nutrition, forager bees, pollen

Introduction

The royal jelly or hypopharyngeal glands of the honey bees are located in the front of the head, with the outflow vessels opening behind the tongue. Their basic function is to secrete the royal jelly which is used to feed worker and drone brood in the initial stage of development, while the queen bee keeps feeding in both the developmental and the adult stages of its life. The glands are set as a cluster and their highest activity is from 6 to 10 days of worker bee's age (Stanimirović *et al*., 2006). After this period, their function decreases and changes in the bees that begin to fly out in the field - forager bees (Kubo *et al*., 1996). Functional and morphological transition from the nursing bees to the forager bees is controlled by juvenile hormone (Jaycox, 1976; Robinson, 1987). In the worker bees hatched at the end of the summer and in autumn, the hypopharyngeal glands function throughout the winter, until spring (Plavša and Pavlović, 2018). For the normal growth and function of these glands, pollen feed is very important in both the larval stage (developmental period) and after hatching (Maurizio, 1961; 1962a). The lack of pollen in the feeding of young bees impedes the function and growth of these glands. If worker bees are later fed normally with pollen, the glands can grow and regain their function (Maurizio, 1962b). Standif (1967) proved that the feeding of bees with red clover pollen more favorably affects the development of the hypopharyngeal glands compared to feeding bees with the same concentration of alfalfa (*Medicago sativa*) and black poplar (*Populus nigra*) pollen. Ohashi *et al*. (2000) found that in

the colonies without queen bee, most of the older bees (80-90%) can retain or restore the function of these glands to the level of functioning as in the nursing bees (age 6-12 days). The amount of synthesized royal jelly was maintained at the level of a normal colony (colony with a queen bee) for at least two months.
The aim of the study was to determine how the additional honeybee bee feeding with pollen in their first days of life (1-10) influences the development of the hypopharyngeal glands. Particular attention was paid to the pollen of the red clover (*Trifolium pratense*) because the pollen-gathering colonies were in the selection stage for the increased foraging of pollen of this leguminous species for more successful pollination.

Material and methods

For this experiment, the honey bees from the apiary of the Institute for forage crops were used. The experiment was conducted in 2014. Bees of age 1-2 days were used for this experiment by separating frames with a capped brood (emerging brood). After 48 hours the bees were hatched from it. These bees were kept in small, glass, experimental hives and fed with a sugar dough in which different pollen was added (15%). Pollen was collected at the time on the red clover in bloom (late June and early July). Pollen was taken by pollen collectors which were set in the production honey bee colonies. After collection, the pollen was dried (in the pollen dryer at 42°C) and sorted by the color as B - beige, Z - yellow, N-orange and S - gray pollen. Pollen of beige color was collected on a red clover (determined by a microscope) while for the other groups of differently colored pollen the origin of the plant species could not be accurately determined. Control treatment was a group of bees fed only with a sugar dough. From each mini-hive, 50 worker bees were sampled for the measurement of the glands. The measurement was done 15 days after feeding. The size of the glands was measured under a microscope (Olympus), using the measurement tile. Total of 250 samples. For all groups of pollen, quality analysis was carried out according to standard methods. All analyzes were done according to the Rulebook (Official Gazette of RS 101/2015). Phosphorus was determined by spectrometric method SRP, ISO (6491/2003), and potassium, macro and micro elements were determined by the AAS method (AAS-Perkin Elmer 1100 B USA). Each sample was done in three repetitions. ANOVA was performed using the computer program Statistica 8.0 (StatSoft) in a completely randomized design in three replications. The treatments were compared to each other by a LSD test at a significance level of 0.01.

Results and discussion

It was found that the size of the hypopharyngeal glands averaged at 7.25 μm. The largest glands were found in bees that were fed with a sugar dough with added red clover pollen (beige pollen). In second place were bees fed with orange pollen, then yellow and at the end were the bee fed with the dough with added gray pollen (Table 1). The smallest glands were determined in bees fed only with the sugar dough (6.53 μm). No protein component (pollen powder) was added to the sugar dough used to feed these. The fact that the bees fed only the sugar component have the smallest glands was also found by DeGrandi-Hoffman *et al*. (2010). They have shown that supplementary diet of pollen can also reduce the additional losses of bee colonies, which is very important for wide beekeeping practice.

Table 1. Average values of the size of hypopharyngeal glands of worker bees (μm), number of bees and standard deviation.

Treatment	Average	Number	Standard deviation

F test	0245**		
Lsd 005 001	0.26 0.42		

* p < 0,05
* * p <0,01
ns - no significance
a, b, c –homogenous groups within which there are no significant differences, and there are significant or very significant differences between groups

After the monofactorial analyzes of variance and comparison by the LSD, it was found that three homogeneous groups were formed according to the size of the hypopharyngeal glands. The largest glands were in bees fed with a sugar dough with beige pollen (pollen of red clover). The size of the glands in this group of bees was an average of 8.17 μm and very significantly differed from other groups of bees. The size of the glands of bees fed with yellow and orange pollen did not differ from one another, and compared to the other two homogeneous groups, they differed significantly. The gland size in the bees fed with gray pollen and in the bees from control did not differ from each other, but they differed significantly from other treatments.

By chemical pollen analysis, it was found that the highest crude protein was in gray pollen (Table 2). This pollen had the highest amount of ash (3.15%), as well as certain macro (P, Ca and Mg) and micro elements (Fe, Zn). Pollen of red clover (beige color) had the most crude fat. The yellow pollen was the richest in K and Mn, and the pollen of orange color had the most crude cellulose.

When considering the influence of pollen quality on the development of the hypopharyngeal glands, it can be noticed that gray pollen, although it had the highest protein content, and most of the macro and micro elements examined did not yield the best results. Although this pollen had the most residue in the analysis, it had the most of the ash. Bees fed with this type of pollen had the least developed hypopharyngeal glands of all bees fed with food with added pollen. They had larger glands compared to control treatment where bees were fed with pure sugar dough. The largest hypopharyngeal glands were found in bees fed with the red clover (beige) pollen. This pollen contained the most crude cellulose and almost the same amount of crude fat as orange pollen (Table 3), but the ratio of other components was well balanced and gave very positive results in the development of the hypopharyngeal glands. This pollen, although it had 6.11% less crude protein and twice less phosphorus (P) and iron (Fe) compared to gray pollen, led to a significantly higher development of the hypopharyngeal glands (19.4%). Feeding bees with red clover has led to an increase in the size of hypopharyngeal glands by 26.1% compared to the control. It is interesting to note that the diet with gray gray, which according to its quality was at the level of bee pollen-bread (Anđelković *et al.*, 2011) and it led to an increase in the hypopharyngeal glands by 4.7% compared to control. This can also be attributed to the high amount of residues that this pollen (crude ash) has, as well as double the higher proportion of individual elements (P and Fe), which obviously have a negative impact on the development of the hypopharyngeal glands.

Table 2. Pollen quality, crude ash, protein, cellulose, fat (%), macro and micro elements.

Conclusion

After monitoring the influence of feeding bees with various types of pollen on the development of royal jelly (hypopharyngeal) glands, the following conclusions can be made:
The measured hypopharyngeal gland size was, on average, 7.25 µm and ranged from 6.53 µm in control to 8.17 µm in bees fed with the red clover pollen.
Three homogeneous groups were isolated from the treatment, and the size of the hypopharyngeal gland of the bees fed with red clover pollen was significantly different in comparison to other treatments.
Although the gray pollen showed the highest values for most quality parameters (crude proteins, macro and micro elements), bees fed with this pollen had larger hypopharyngeal glands compared only to the control treatment.
The size of the glands in bees fed with red clover pollen was 26.1% higher than in the control (bees fed only with the sugar dough).

Abstract

The concentrations of Chromium (Cr) in fish from the river Vardar have been investigated in order to assess safety for consumers and the level of contamination. The selected tissues (muscle**,** liver and skin) of two fish species: Europian Chub (*Squalius cephalus*) and Common barbel (*Barbus barbus*) from river Vardar stream, Republic of North Macedonia. Samples are collected in nine different points (Hot Spots) in total distance of 301km and approximate 33km between sampling sites. The effect of environmental conditions and urban discharges on Chromium (Cr) accumulation in muscles, liver and skin were investigated. The metal analyses were performed using Inductively coupled plasma mass spectrometry (ICPMS). The average of metal concentrations (micrograms per gram wet weight) in nine hot spots (HS) occurred in the following ranges:HS-1: muscles 0.25 - liver 1.00 - skin 0.10, HS-2: muscles 0.25 - liver 0.70 – skin 0.20, HS-3: muscles 0.10 - liver 0.30 - skin 0.10, HS-4: muscles 0.15 - liver 2.40 – skin 0.10, HS-5: muscles 0.10 - liver 0.54 - skin 0.04, HS-6: muscles 0.10 – liver 0.20 - skin 0.00, HS-7: muscles 0.10 - liver 1.00 - skin 0.10, HS-8: muscles 0.14 - liver 1.40 - skin 0.00 and HS-9: muscles 0.15 - liver 1.35 - skin 0.00. The lowest levels of the Chromium (Cr) were detected in the skin. The muscles and liver were found to accumulate the highest amounts of Cr. In the case of organs, the highest levels were found, as follows: liver > muscles > skin. Further investigation of heavy metals is recommended, including a survey of fish consumption frequency among the local inhabitants.

Keywords: *heavy metals, Chromium, fish tissue, Republic of North Macedonia*

Introduction

Fish is an important part of the human diet, but also a good indicator of trace metal pollution in the aquatic ecosystem. Fish samples are considered as one of the most indicative factors, in fresh water systems, for the estimation of trace metals pollution potential (Rashed,2001).Organisms retain Cr, through gastrointestinal system in to the liver, soft tissue muscle to deposite in the end at the kidney, gills, ovaries and testes. Pollution of water bodies is becoming a major cause of concern with respect to human health (Jarup, 2003).Heavy metal from anthropogenic pollution source are released in to the aqua systems ,and then heavy metal become serious threat because of their toxicity, long persistence bioacumulation and biomagnifications in the food chain (Eisler, 1988). Metals in waters may be of natural origin from the rocks and soil or from human activities, including industry, domestic wastewater, agricultural discharge, mine runoff, solid waste disposal and atmosphere aic deposition. Metals generally enter the aquatic environment through atmospheric deposition, erosion of the geological matrix, or due to anthropogenic activities caused by industrial effluents, domestic sewage, and mining wastes.

Increase in the human population has greatly contributed towards the conversion of these water bodies to impending contamination sinks (Tarvainen et al., 1997; Stephen et al., 2000).

Heavy metals are well known to be non-biodegradable and when present at high concentrations, they tend to bioaccumulate (De Forest et al, 2007).Being non-biodegradable, metals can be concentrated along the food chain, producing their toxic effects at points often far away from the source of the pollution (Fernandez et al., 2000). Heavy metals can cause a variety of ailments in humans depending on the degree of exposure. These vary from minor skin irritation to severe damages of the liver, kidney, skeleton, nerve tissues and circulatory system. Liver and muscle are usually used as a targeted tissues for the analysis of the heavy metal concentration, according to the studies carried out with the different fish species have shown that trace metals are accumulate mainly in metabolic organs such as the liver, where metal are stored for detoxication through the metalothioniens (Carpene and Vasak,1989;Kargin and Erden 1991;Hogstrand and Howx,1991)

Chromium (Cr) is a heavy metal but is essential as an enzyme cofactor, which may become a very toxic when accumulating in the important organs like liver and spleen (Wagner and Boman,2003).Chromium is an essential nutrient metal, necessary for metabolism of carbohydrates. Chromium entering the aquatic ecosystem thru discharges from the lether industries, metal finishing, electroplanting, mining, printing industries, pharmaceutical industries, etc. Poor treatment of these effluents can lead to the presence of the Chromium in the water bodies as a Cr (VI) where it can be commonly found in the high level concentration and potentially harmful for the fish. Hexavalent Cr (VI) is considered to be toxic because of its power to potentially oxidate and ability to cross cell membranes (WHO, 1990).

River Vardar is the longest river in the Republic of North Macedonia and Republic of Greece with distance of over 388 km, with his source in the location Vrutok and stream at the Aegean sea. The river Vardar, with its tributaries, makes up a great part of the total water resource of North Macedonia. These tributaries and river Vardar are directly or indirectly connected with the mining areas and foundry for Chromium (Cr) in the locations. The first reported information about ichthyo fauna of river Vardar vas from Steindachner (1892) and then he describe the Leucos macedonicus from the river Vardar. Some fish species in the river Vardar (Squalius cephalus,Barbus Barbus, Vimba vimba) are good examination samples for pollution because they are in the all stream of river.The ichthiofauna of the Vardar river is important part of the aquatic food chain for their omnivores way of feeding. The river is widely used for fisheries (wild fish and fish farming), sports and recreation. Very little recent information is available regarding the contamination with metals in the Vardar river fish species. The river Vardar passes near and across the biggest cities including Gostivar, Tetovo, Skopje, Veles, Negotino, Demir Kapija and Gevgelija with possibility of environmental contamination from domestic and industrial sewage Hot point spots in Fig.1.

Fig.1 In the map of the Republic of North Macedonia, showing hot point spots

The aim of this study is to provide information and evaluate the level of Chromium (Cr) as a heavy metal in fish organs (muscle, liver and skin) from Europian Chub (*Squalius cephalus*) and Common barbel (*Barbus barbus*) fish species.

Material and methods

Samples were collected in nine (9) places with distance between them in around 33km along the river Vardar. From each place fishes were collected from both species with support from fishermen’s licensed for sport fishing in the North Macedonian fishing Federation.

Fish samples were transported with the plastic bags set in transport refrigerator in laboratory submitted for dissection of target organs were collected for study including skin, liver and muscle. Each sample of fish tissue has been measurement with analytical scale then set in plastic bag, marked with number which show the catching location and tissue then finally refrigerated below the -18ºC.Total numbers of samples were sixty (60) from Europian Chub and Common barbell.

The next step was the sample to set in the porcelain pots then the sample was heated in microwave in 105°C for 24h to drain. The next day the samples were taken out from microwave and they passed to the stove for 24h in 550°C where they were burned. After 24h the burned samples are prepare for digestion with HNO3 65%.Prepared sample after digestion are ready for reading and analyze by Inductivly coupled plasma mass spectrometry with the ICP-MS type Agilent 7500 series. All data are presented in the unit mg/kg wet weight of a sample tissue.

Results and discussion

Results of this study showed that the metal concentrations accumulated in the tissue samples were in descending order of liver > muscles >skin. In the study, we found that the concentration of Chromium (Cr) were different in the analyzed organs and differently in the sampling locations. The average of concentration of the Chromium (Cr) in the organs (muscle, liver and skin) and the locations (nine locations) is showed in Table 1.

Table 1. Mean Heavy Metal Content (mg/kg wet weight) in Fish muscle, liver and skin

Sampling point	Muscle	Liver	Skin
HS-1	0.25	1.00	0.10
HS-2	0.25	0.70	0.20
HS-3	0.10	0.30	0.10
HS-4	0.15	2.40	0.10
HS-5	0.10	0.54	0.04
HS-6	0.10	0.20	0.00
HS-7	0.10	1.00	0.10
HS-8	0.14	1.40	0.00
HS-9	0.15	1.35	0.00

Higher Chromium (Cr) concentrations were found in liver tissue, while the lowest were detected in skin tissues. This finding is in agreement with those of other studies regarding the differences between heavy-metal accumulation in fish tissue (N. Biba, J. Mavromati, 2014).
There guidelines on acceptable levels of in Chromium (Cr) the edible parts of fish suggested in North Macedonia is according to international standards 0.73 mg/kg (IAEA) and the 2< mg/kg (Chine). According to results, there is metal contamination, but it is higher than the guidelines, in the edible part of the examined fish. The examined fish were not associated with enhanced Chromium (Cr) content in their muscle and were safe within the limits for human consumption. From results it can be seen that authors obtained a different Chromium (Cr) concentration, and as we can see that highest level is in the HS-4 sampling site, which is the point where the river Lepenci is connected to the river Vardar, waste water and atmospheric water from capitol city Skopje is load to the river Vardar, the uper part between city of Veles and Skopje, so it is expected to have registered Chromium (Cr) pollution. In the most studies of similar analyzed samples, the liver accumulate the highest concentration of Chromium (Cr) in our study is shown also that is the samples of liver in sampling sites HS -4 and till the HS-9, showed that fishes in the part of river Vardar from Skopje till the border with Republic of Greece accumulated higher concentration of Chromium (Cr). In previous study, increased concentrations of these hazardous substances also, especially Pb and Cd, in water and sediment from the lower part of the Vardar River, influenced higher accumulations of metals in liver, gills and gonads of Gobio gobio L. (Nastova, et al. 2017), concentration of Chromium (Cr) in skin is not reported.
In our country the river pollution with heavy metal contaminations are in the concern because off potential thrived waste from domestic and industrial sewage, non-secured industrial landfill and mining fields. The Chromium (Cr) are regarded as potential hazards that can endanger both animal and human health. Knowledge of their concentrations in fish is therefore important both with respect to nature management and human consumption of fish as suggested in (Amundsen et al. 1997).
In Vardar river, among all river aquatic organisms the fish are the most interested for humans for sport activities in particular, source of food mainly for fisherman's and their families as well. Fishes are considered as indicators in river ecosystem for heavy metal contaminations with light level risk as a potential for human food consumption, because fish are in the top of aquatic food chain, heavy metal accumulation and possibly for the transfer heavy metals on the humans.

Conclusion

Preliminary results provide information for the levels of Chromium (Cr) in common fish species of the river Vardar. Results will contribute to the effective monitoring of both environmental quality and the health of the organisms inhabiting the river ecosystem. According to the fish sample analyses the range of concentration with Chromium (Cr) in the higher border with the range of international standards 0.73 - 2 mg/kg wet weight, and it shows that the fishes from investigated Vardar river are safe for human consumption.

Aquatic organisms have been widely used in biological monitoring and assessment of safe environmental levels of heavy metals. In this study concentration of Chromium (Cr) in the muscle of both fish species were used to investigate possible transfer of Chromium (Cr) to human populations via fish consumption. Since accumulation of metals in the biological system is dangerous to human beings in our country, there is a need for regular or continuous monitoring of heavy metals concentrations in the aquatic environments.

Abstract

For the assessment of the population structure, evaluation of the genetic relationships and possible admixture between breeds the Bayesian clustering algorithm was used. Genetic analyses of relationships and admixture were performed in the local maintained population of Slovak Spotted cattle (N=85). The loss of diversity due to the rapid decrease of the population's size and the unequal use of founders was indicated by pedigree analysis before. To analyse the level of admixture, genotyping information of other, closely related breeds involved in the formation of Slovak Spotted cattle were used; Holstein (N=99), Swiss Simmental (N=78), Pinzgau (N=151) and Ayrshire (N=10). After LD pruning ($r^2 \leq 0.05$) final dataset consisted of 423 animals and 5,770 SNP markers. Generally, the F_{ST} (in average 0.15) index showed low value of genetic differentiation among evaluated populations mainly due to their common historical origin and high values of gene flow. Unsupervised analysis of population structure resulted in the most likely expected cluster number K=3–5. The graphical visualization of K=5, the likelihood that the individuals belong to the respective five populations, allowed to describe genetic variability and admixture of respective breeds. Observed changes among membership probability pointed out that the Slovak Spotted is closest to the Slovak Pinzgau cattle. Even both breeds having different history, selected set of SNPs could reflect the relationship to the authentic cattle living in Carpathians. Gene flow of Holstein, Ayrshire and Swiss Simmental in formation of Slovak Spotted could be proposed.

Key words: *admixture, Slovak Spotted cattle, population structure, Wright fixation index.*

Introduction

The genetic diversity is an important tool which allows for the genetic improvement of animals with respect to their economically important traits (Melka *et al.*, 2013). For the estimation of genetic diversity are used multiple methods including evaluation of genetic structure. According to Andam *et al.* (2017) the genetic structure represents the organization of genetic variation which is directed by combined effects of mutation, genetic drift, recombination, demographic history and selection.

To analysing population structure was developed of several statistical methods, among the most common belong admixture-based clustering (Pritchard *et al.*, 2000; Alexander *et al.*, 2009). Various methods are available for the evaluation of genetic admixture proportions in populations; often used the Bayesian algorithm STRUCTURE (Pritchard *et al.*, 2000) and principal components analysis (Patterson *et al.*, 2006). Analysis of admixture represents an important tool which can be applied on genomic data to study genetic background of local population. It can be defined as a phenomenon that can occur as a result of introgression and hybridization of individuals, populations or species (Kadlečík *et al.*, 2017b). Using this indicator, it is possible to explain the historical or geographical origin of an animal. According to Kasarda *et al.* (2015) different histories among the populations can affect the frequency of allele among populations of the genome and this deviation may be analysed for example by F_{ST} index. Wright's F_{ST} index (Wright, 1931) is an indicator that represents the degree of population differentiation resulting from the genetic structure. At the beginning, the

F_{ST} index was defined as the relationship between two random sampled gametes from the same subpopulation in the case the correlation between two sampled gametes from the total population was set to zero. Currently, more definitions of F_{ST} are available that are based on a variety of different conceptual formulations but with a focus on rating some aspect of population differentiation (Holsinger and Weir, 2009). Development of new technologies was increased potential for exploring genetic diversity, population structure as well as the common history of populations. To ensure the breeding goal of Slovak spotted cattle, it is advisable to know the extent of admixture of other breeds. In this study, SNP high-density data were used for evaluation of genetic diversity, population structure and admixture in four cattle breeds, which have contributed to the formation of Slovak Spotted cattle.

Materials and Methods

The analysis consisted of a total of 423 cattle genotypes from 5 breeds and was comprised of an SNP array dataset, which was created from a combination of new data and previously published data. The genomic information about Holstein (N=99), Swiss Simmental (N=78), Slovak Pinzgau (N=151), Ayrshire (N=10) and Slovak Spotted (N=85) was obtained by two platforms: Illumina BovineSNP50v2 BeadChip and ICBF International Dairy and Beef v3. (McTavish *et al.*,2013a). The quality control of SNP data was done by using program PLINK v1.9 (Chang *et al.*, 2015). From the database were excluded SNPs with unknown chromosomal position according to the latest bovine genome assembly (Btau 5.0.1) and markers located on sex chromosomes (Moravčíková *et al.*, 2017). The remaining individuals were then subjected to the next quality control. SNPs with a call rate of less than 0.90 and minor allele frequency (MAF) of 0.05 were excluded from the dataset and remained 39 934 SNPs. Some SNPs that were in high linkage disequilibrium (LD) were pruned out using command indep-pairwise 50 5 0.05 by software PLINK v1.9. This command left 5 770 SNPs for further analysis. Kijas *et al.* (2009) reported that pruning of SNPs in high LD prevents ascertainment bias and generate a meaningful comparison between breeds. To infer the genetic structure and the degree of admixture were used the Bayesian clustering procedure adopted in STRUCTURE v2.3.4 software (Pritchard *et al.*, 2000). The analyses were run in ten replications separately from K=1 to K=10. The individual simulations consisted of the burn-in period of 1000 followed by Monte Carlo Markov chain (MCMC) simulations steps of 10 000 iterations. The results were exported to STRUCTURE HARVESTER (Earl and von Holdt, 2012), which implements the Evanno's method to infer optimal number of clusters (K) in analysed dataset (Evanno *et al.*, 2005). The value of the K and values of log probability of the data (L [K]) for each cluster were estimated.
Genetic differentiation among populations was estimated using Wright fixation index according to Weir and Cockerham (1984). Akey *et al.* (2002) reported that the F_{ST} index is one of the most appropriate parameter to describe the genetic differentiation among subpopulations (values move range from 0 to 1). For calculation of F_{ST} index, program R and package StAMPP (Pembleton *et al.*, 2013) was used.

Results and Discussion

The algorithm was primarily focused on identifying related individuals without a reference to prior information of the genetic division. The aim was to determine the degree of genetic admixture among the 5 evaluated cattle populations. For determination of the genetic population structure of each evaluated breed and estimation of admixture level among them the correlated allele frequencies model was used. The results of Delta K showed that the optimal number of clusters, which represents most similarly ancestor of breeds, ranged from K=3 to K=5. The membership probabilities at the K=3 indicated formations of three genetically separated clusters; first composed from Swiss Simmental, second from Holstein and Ayrshire, and the last one composed from Slovak Spotted and Slovak Pinzgau cattle (Figure 1A). At the K=5 (Figure 1B), Slovak Spotted and Slovak Pinzgau breed were divided into two separate clusters. In Figure 1, each animal represents one vertical line which is split into K coloured segments. The mixed colours reported information about the level of admixture for individually predefined populations of K among 3 and 5.

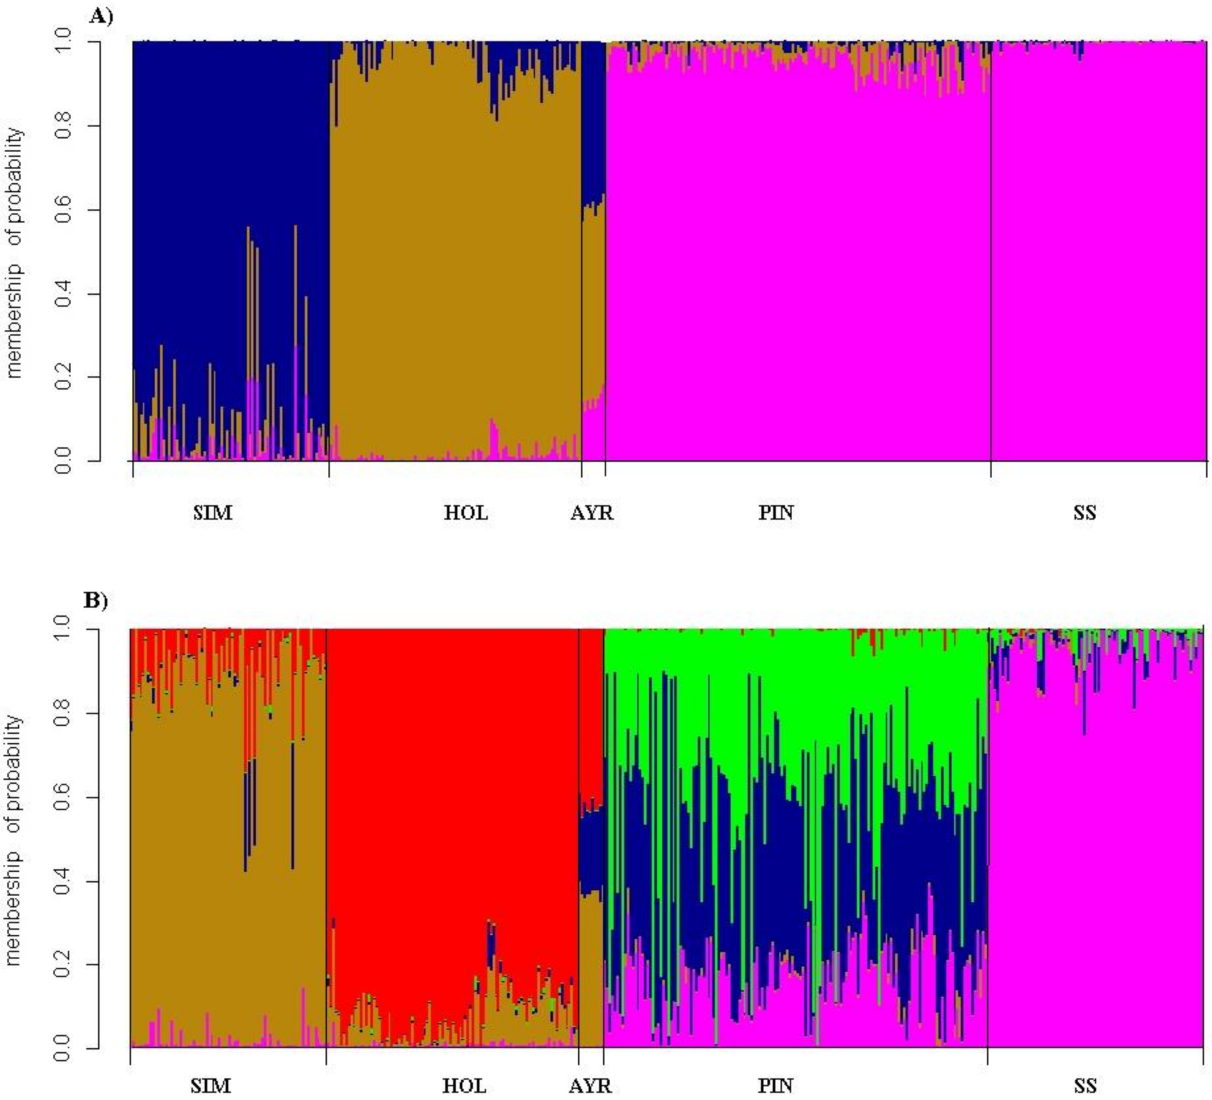

Figure 1 Results of the Bayesian clustering analysis implemented in STRUCTURE v 2.3.4 (Pritchard *et al.* 2000) analyses inferred using the ΔK statistic of Evanno *et al.* (2005) for the five cattle breeds. A. K=3 yields the highest value of ΔK. Three groups corresponding to K=3 are shown here. B. K=5 yields the highest value of ΔK. Three groups corresponding to K=5 are shown here. Each individual is represented by a vertical line, which is divided into K coloured segments that represent the individual's estimated membership proportion in each of the clusters. SIM – Swiss Simmental, HOL – Holstein, AYR – Ayrshire, PIN – Slovak Pinzgau, SS – Slovak Spotted.

Figure 1A showed among the evaluated breeds low level of the admixture, especially for the Slovak Spotted and Pinzgau breeds, with neglectable representation of other breeds. Slovak

Spotted and Slovak Pinzgau had the highest membership probability in the fourth and fifth cluster.
In the first cluster, the highest membership probability of Swiss Simental was found, while within the other clusters this breed showed only a low proportion, except for the Ayrshire breed. In the second cluster, the highest proportion reached the Holstein breed. This cluster showed the representation of Simental and Ayrshire breeds, but the values of membership probability not exceeded 20%. The Ayrshire breed in the third cluster pointed out a higher proportion of admixture, but the small number of individuals (N=10) it is not enough to fully confirm the genetic composition of this breed. The highest value of membership probability for Ayrshire breed was assigned in the fourth cluster, while this breed was involved in the grading-up process of Slovak Pinzgau cattle (Figure 1B). On the contrary, in the K=5 (Figure 1B) it can be seen, that the Slovak Pinzgau cattle in the fourth cluster had a high level of admixture. The Ayrshire breed reached highest representation, which exceeded more than 50%. In addition, the low representation of Simental and Holstein can be seen, but neither breed exceeds 20%. The last cluster represents Slovak Spotted cattle. Figure 1A indicated the low representation of Swiss Simental and Holstein, but Figure 1B showed representation of all evaluated populations.
The results reflected mainly the history of cattle breeding in Slovakia. The current genepool of the Slovak Spotted and Slovak Pinzgau cattle was affected by various breeds including extincted autochthonous Carpathian Red and Carpathian Grey cattle (Kasarda *et al.* 2015) with Swiss Simmental, Austrian Pinzgau, Holstein and Ayrshire. Based on our results the Slovak Spotted is more related to Slovak Pinzgau (Figure 1A) than Ayrshire in comparison to Swiss Simental. The reason may be a significant "grading-up" in recent years, as stated by Šidlová *et al.* (2015). Especially after 1972 due to efforts to increase milk production, bulls of the Ayrshire and Holstein breeds were used in the breeding. This can also be seen in Figure 1B. Obtained results pointed out certain signals of admixture between the Holstein and the Swiss Simmental breed. Signer - Hasler *et al.* (2017) reported admixture, where Swiss Simmental was clearly divided from Holstein breed, although those breeds share common ancestors. Kim and Rothschild (2014) examined admixture between Holstein and Ayrshire, which are used in improvement of multi-purpose breeds globally and have common ancestors. Results reflects the history of these two breeds. Similar conclusions were reported by Šidlová *et al.* (2015).

Table 1 Wright F_{ST} index among evaluated breeds

	SS	**AYR**	**HOL**	**SIM**	**PIN**
SS					
AYR	0.198				
HOL	0.157	0.089			
SIM	0.192	0.102	0.085		
PIN	0.032	0.21	0.167	0.192	

Wright (1978) and Hartl and Clark (1997) introduced that the F_{ST} values up to 0.05 indicated low genetic differentiation among evaluated populations. The F_{ST} values in range 0.05–0.15 reported about moderate differentiation and value from 0.15 to 0.25 suggested relatively high genetic differentiation in metapopulation. The values >0.25 indicated very high genetic differentiation.
The results showed that the F_{ST} values were lowest between two Slovak breeds (Slovak Spotted - Pinzgau cattle) compared to other (Table 1). The highest differentiation was found between Ayrshire and Pinzgau breed. The highest differentiation was found between Ayrshire and Pinzgau breed. The lower value was expected due to the fact, that the Pinzgau breed

undergone grading up with Ayrshire breed among 1971–1989. In the same period, Pinzgau breeding bulls and semen from Austria were imported which could cause such a high differentiation. Kasarda *et al.* (2018) confirmed a common genepool of Slovak and Austrian Pinzgau (F_{ST} = 0.13). Kadlečík *et al.* (2017a) which evaluated pedigree data of Slovak Spotted cattle through Wright fixation index confirmed genetic differentiation (F_{ST} =0.098) among subpopulations.

Obtained results of F_{ST} values for other evaluated breeds expressed high differentiation, which was based on how these breeds were involved in the formation of Slovak Spotted breed. Signer – Hasler *et al.* (2017) estimated slightly higher F_{ST} index between Swiss Simmental and Holstein (0.142). This could be related to the fact that Holstein was involved in formation Slovak Spotted breed, but not as much as up to that extent like for the Swiss breeds. Based on our results Ayrshire breed reached values of F_{ST} close to 0.2 which could indicate higher incidence of heterozygotes in the subpopulations. Our results were consistent with the results of Kim and Rothschild (2014) which confirmed the higher incidence of heterozygotes in the F1 generation of evaluated breeds. The F_{ST} results confirm the occurrence of genetic differentiation between the subpopulations. However, none of the subpopulations has reached a higher representation than 0.25. Our results reached slightly lower values, which indicates a higher presence of homozygotes in the evaluated subpopulations. Between two local Slovak Spotted and Slovak Pinzgau populations low genomic differentiation was found. This information can be used in the selection strategy or conservation programs for the Slovak Spotted Breed within the strategy of small homeland heritage.

Conclusion

Results showed low level of genetic differentiation as well as particular gene flow among analysed breeds. This study provides new information about the level of admixture and genetic structure of evaluated breeds occurring in Danubian region. In five evaluated breeds were found discrete genetic features, which should be taken into account in conservation programs in regard of preservation of genetic diversity. The negligible value of genetic differentiation was found within the Slovak Spotted and Slovak Pinzgau cattle genome, which can be due to the common selection history. In the future, priority on increasing genetic diversity and population size should be given, including the active exchange and use of proven sires of sires and sires of dams.

Abstract

The aim of this study was to evaluate changes in the free testosterone saliva (TSL) in pigs under stress and its relation to behavior. Fifty-five pigs were tested (28 gilts and 27 barrows). Males were castrated in 2nd week after birth. Behavior in new room was tested in open-field arena. Test lasts 20 minutes and was recorded by one camera. Saliva samples for TSL analyses were sampled in calm state before testing and immediately after test. Behavior was analyzed from records using Noldus Observer XT software. TSL were measured by ELISA method. TSL in calm state varied from 78.91 pg/mL to 621.37 pg/mL and from 93.12 pg/mL to 1589.36 pg/mL after stress situation in new room. There was not difference in TSL between gilts and barrows. TSL after stress was higher than TSL in calm state in 34 animals (group I), and in 21 animals (group D) TSL after stress was lower than TSL in calm state. For group I TSL in calm state did not correlate with TSL after stress ($r = 0.191$, $P = 0.278$). For group D TSL in calm state correlate with TSL after stress ($r = 0.603$, $P = 0.004$). Analysis did not show difference in behavior between I and D group. Despite no difference in behavior, correlation analysis detected small difference in relation between evaluated behavior traits and TSL in calm state as well as after stress. ANOVA by TSL quartiles in calm state did not show difference between pigs with low and high TSL values. ANOVA by TSL quartiles after stress discovered significant difference in total duration standing between pigs with the lowest (Q_1) and the highest (Q_4) TSL.

Keywords: *Pig, Piglet, Behavior, Open-field, Testosterone.*

Introduction

The testosterone plays role in many physiologic and metabolic processes, from the prenatal period to the end of life. The testosterone has impact to the development of male reproductive tissues, promotion to secondary sexual traits, body growth and mass, health status and well-being (Prader 1962, Colenbrander et al., 1978, Mooradian et al., 1987, Traish, 2014, Caliber and Hackett, 2019). The testosterone level is affecting the brain development, social and sexual behavior, as well as orientation behavior (Arnold and Breedlove, 1985, Cronin et al., 2003, Fredriksen, et al., 2004, Albrecht et al., 2012). The testosterone become play important role in the pork production in the recent years. Public as well as scientists concerns to the surgical castration as source of the pain with issues to the growth and welfare (Dunshea et al., 1993, Prunier et al. 2005, Fredriksen et al., 2011, De Briyne et al., 2016). The entire males number for pork production is increasing in the Europe, but it leads to risk boar-tainted carcasses (Schanbacher et al., 1985, Bee et al., 2015). Heritability of the boar taint components allows use effective selection in the breeding programs (Willeke et al. 1980, Ducro-Steverink, 2006, Squires 2006, Tajet et al., 2006, Winding et al., 2012, Robic et al., 2012, Lervik et al., 2013, Haberland et al. 2014). Promptly prediction of the steroid levels in young animals could be useful for the selection beneficial for elimination the boar taint problem, particularly in the breeding. Testosterone changes under stress are often investigates mainly in human, but results are inconsistent. A source of this inconsistency may be a nature of stress triggers (Bedgood et al., 2014). Choi et al. (2012) reported the significantly decrease salivary testosterone in men under stress from pain. On the contrary Bedgood et al. (2014) presented increasing testosterone level under social stress in men, but in connection to basal levels of cortisol. Higher levels of the testosterone found Lane et al. (2015) in men after physical exercise. Psychological stress significantly increased the testosterone levels in men but no significant decrease in women (Afrisham et al., 2016). Some animal model studies are reported in study Edinger and Frye (2005). Authors suggested effect of the testosterone anti-anxiety and analgesia and in behavior change under stress. The aim of this study was to evaluate changes in the salivary testosterone levels under stress and its relationship with behavior in new, unknown room in pig.

Materials and methods

Animals and housing

Experiment was carried out at the Experimental Centre for Farm Animals (ECFA) of Slovak University of Agriculture in Nitra. Fifty-five pigs Large White with live weight from 18.5 kg to 27.5 kg were tested (28 gilts and 27 barrows). Males were castrated in 2nd week after birth. All procedures related to animals were performed in accordance with guidelines of the Slovak University of Agriculture Ethics Committee. Pigs were housed in pairs in the pens measuring 3100 mm × 1070 mm. The pen has solid floor without bedding, metal walls, metal barns in front and metal gate in back. Floor was cleaned twice a day. Feed was provided ad libitum due automatic feeding system. Feed mixture was prepared individually for each pen by average daily gain. Gain was calculated from weekly weighting. Water was provided due nipple drinker, one in each pen.

Behavior test

Behavior in new room was tested in the open-field arena in same stall at ECFA. The open-field arena measured 4000 mm × 4000 mm is acoustic insulated, has solid walls, door and one window with mirror glass above animal area, window border is 120 cm above floor. Adjacent room is observation room, observer can see to the open-field arena though window. Arena was cleaned between tests to reduce odor from the pig in the preceding test. For the behavior test each pig was picked up from the pen, gently moved to the opened entrance door to open-field arena and let to enter it and door was closed. Test lasts 20 minutes. After 20 minutes assistant enter open-field area and collects saliva. After saliva collection pig was moved back to the pen. Behavior was recorded from CCTV system, camera was mounted above arena and connected to PC in observation room. The Noldus Observer XT 11.5 software was used for behavior analysis. Latency of standing (LS) and locomotion activity was scored: moving (M), standing (S) and lying (L). Initiate behavior was M. Behavior was recorded by continuous recording, M, S and L behavior was scored as state event, latency of standing as point event.

Saliva collection and testosterone analysis

Saliva was collected in calm state (C), approximately 30 minutes before open-field test and after stress (S), immediately at the end of open-field test. Saliva was collected by allowing the pig to chew sterilized cotton tampon until it was moistened (about 60 seconds). Tampons were pre-prepared and stored in sterilized laboratory glass tubes. Moistened tampon was placed back to tube and centrifuged 15 minutes at 3000 rpm. Collected saliva was filtered and stored at -20ºC until analysis. The testosterone level was measured by ELISA method, commercial kit Dia Metra Testosterone saliva was used. Optical absorbance was measured by Microplate Reader Model DV 990BV4, UniEquip Deutschland.

Statistical analysis

Difference in testosterone levels in calm state (TSLC) and in stress state (TSLS) between gilts and barrows (tested by t-test for independent samples) was not significant and therefore disregarded in all other analysis. The TSLS was higher than the TSLC in 34 pigs (group I), and in 21 pigs (group D) the TSLS was lower than the TSLC. Difference in the sex ratio in I and D group was tested by chi-square test and was not significant. Differences in the TSLC and the TSLS in whole group (n = 55) and groups I (n = 34) and D (n = 21) were compared by paired t-test. Difference between I and D groups in TSLC and TSLS was tested by t-test for independent samples. Relation between TSLC and TSLS was evaluated by Pearson Correlation coefficient. Behavior in open-field arena was evaluated by LS, total duration (TD), mean duration of bout (M), total number of bouts (TN) of M, S and L. Difference in behavior between I and D groups was tested by t-test for independent samples. Relation between behavior and TSLC as well as TSLS was evaluated by Pearson Correlation coefficient. Difference in behavior among pigs with various TSLC and TSTS was tested by One Way Analysis of Variance (ANOVA), with quartile classification as fixed factor. Statistical analysis was performed with IBM SPSS version 20.

Results and discussion

The TSLC in whole group (n = 55) ranged from 78.91 pg/mL to 621.37 pg/mL, mean value was 297.714 pg/mL and s.d. was 130.671 pg/mL. Moya et al. (2008) reported very similar testosterone levels in pig from 3 weeks to 8 weeks of age (mean = 290 pg/mL, s.d. = 40 pg/mL). The TSLS in whole group (n = 55) ranged from 93.12 pg/mL to 1589.36 pg/mL. The mean value TSLS was significantly higher than TSLC (TSLS mean = 394.98 pg/mL and s.d. = 273.102 pg/mL, $P < 0.05$). Six piglets had TSLS higher than average TSL in non-castrated males in paper Moya et al. (2008). Similar changes in levels of testosterone after stress in men reported Choi et al. (2012), Bedgood et al. (2014), Lane et al. (2015) and Afrisham et al. (2016). Choi et al. (2012) presented decrease but other authors increase. Testosterone level in women after stress was lower, but no significant in paper Afrisham et al. (2016). Interesting fact in our investigation is the TSLS was higher than the TSLC only in 34 pigs and in 21 pigs the TSLS was lower than the TSLC. Difference between groups I and D in mean values of TSLC and TSLS was significant as well as difference between TSLC and TSLS in groups I and D (Tab. 1). Difference between gilts and barrows ratio in group I and D was not found (Tab. 2).

Table 1. Saliva testosterone levels in group I (n = 34) and group D (n = 21).

	Mean TSLC [pg/mL]	s.d. TSLC [pg/mL]	Mean TSLS [pg/mL]	s.d TSLS [pg/mL]
Group I	248.611*	113.084	493.513*	306.414
Group D	377.213*	119.446	235.451*	56.879

* P < 0.001

Table 2. Gilts and barrows ratio crosstabulation by TSL change after stress (n = 55).

		Group I	Group D	Total
Gilt	Count	17.0	11.0	28.0
	Expected Count	17.3	10.7	28.0
Barrow	Count	17.0	10	27
	Expected Count	16.7	10.3	27.0
Total	Count	34.0	21.0	55.0
	Expected Count	34.0	21.0	55.0

$\chi^2 = 0.029$, $P = 0.864$

The TSLC and the TSLS correlate only in group D ($r = 0.603$, $P < 0.01$), in whole group (n = 55) and in group I did not correlate ($r = -0.068$, $P > 0.05$, $r = 0.191$, $P > 0.05$ resp.).

Comparison of means of evaluated behavior traits by t-test did not show difference between I and D group. Despite no difference between means, correlation analysis discovered some minor differences in relation between TSL and some behaviors. The TSLC significantly correlate with TDS (r = -0.464, P < 0.01), ML (r = 0.369, P < 0.05), TNM-0.469, P <0.01) and TNS -0.501, P < 0.01) in group I. The TSLS significantly correlate with TDL (r = 0.402, P < 0.05), ML (r = 0.463, P <0.01) and LS -0.367, P < 0.05) in group I. The TLSC significantly correlate only with ML (r = 0.481, P < 0.05) and the TSLS significantly correlate with MM (r = 0.469, P < 0.05) and TNS (r = -0.507, P < 0.05) in group D. Because of small frequency of lying (28 pigs do not lie down and 19 piglets showed one lying bout) important difference is in TDS, TNM, MM and LS. The correlation between the ML and the TSLS over all group (r= 0.434, P = 0.001, n = 55) suggests connection between lying and testosterone level in stress. Comparison of behavior by ANOVA with fixed factor TSLS quartile classification discovered significant difference in TDS and LS between pigs with the highest TSL and pigs with low TLS in stress. Animals with the highest TSLS shower significantly shorter TDS and LS (Fig. 1, 2).

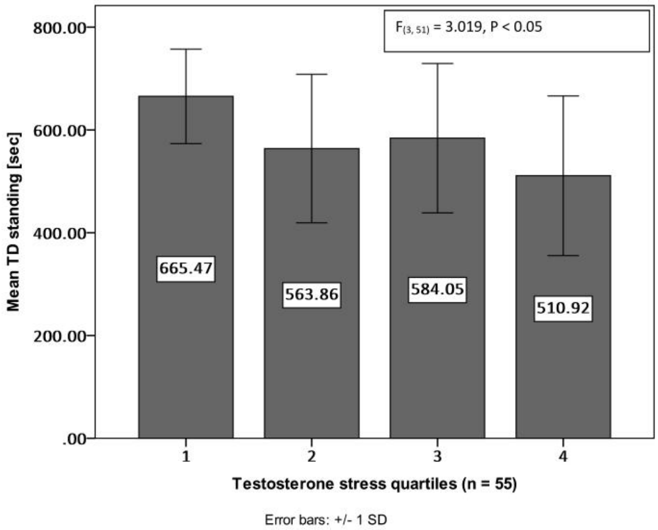

Figure 1. Mean values of the total duration standing in piglets divided to groups by the saliva testosterone level in stress quartiles.

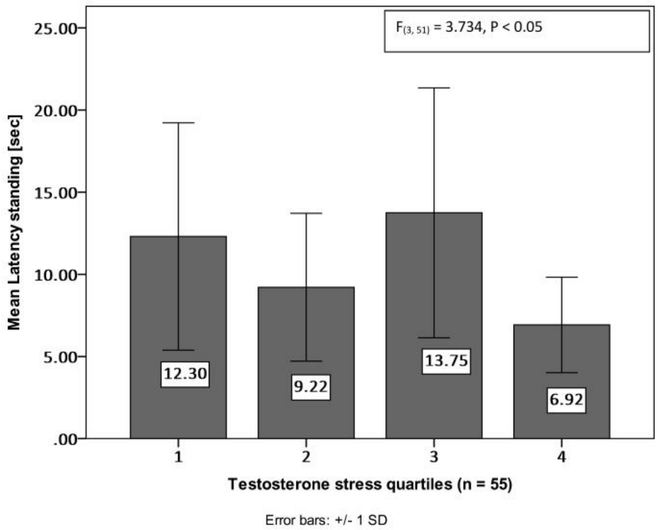

Figure 2. Mean values of the latency standing in piglets divided to groups by the saliva testosterone level in stress quartiles.

Behavior of pigs with the highest TSLS (shorted standing and longer lying) can be considered as expression of less anxiety. The role of higher levels of TS and other androgens in modulation anxiety in human as well as animals suggests many authors (Choi et al. 2012, Bedgood et al., 2014, Lane et al., 2015, Afrisham et al., 2016, Edinger and Frye, 2005). Rats with higher TSL in the open-field tests showed more exploratory behavior, less freezing (Edinger and Frye, 2005. Unfortunately, difference in the behavior is not enough to reliable detection of the pigs with high TSLS, because of variability (Fig. 1, 2). Comparison of behavior by ANOVA with fixed factor TSLC quartile classification did not show difference between pigs with low and high TSL values.

Conclusion

In summary, results suggest the TSL in pigs is changed in stress. Generally, TSL after stress is higher than in calm state, but in some animals is direction of change opposite and TSL after stress is lower. Source of this change is unknown and should be investigated. There is not difference between gilts and barrows in direction of change. The TSL in stress in some animal is higher than in non-castrated males. Change is probably very short in time, but in case of long term stresses the relation of quality of pork and TSL should be investigated in next research. The TSL correlates with some behaviors, but relationship is not very strong. Difference in evaluated behavior traits between animals with low and high TSL is not very expressive. I next research not only the total duration of behaviors but the course in time series during tests should be considered.

Abstract

Agriculture is a source of livelihood for increasing population in the world. It provides mainly food and is expected to avail enough income to farmers and thus improve their livelihood through the increased yield. This study attempted to assess the effects of crop production and food consumption on farmers' welfare. We used secondary data collected at national level during the Fifth Integrated Household Living Conditions from October 2016 to October 2017. For data analysis, Chi-Square test, Pearson's correlation coefficient, t test, and ordinary least-squares (OLS) methods were used. The results revealed that the crop output increased with the increase in inputs (labour, fertilizers, pesticides, and seeds). The return to scale of crop production was 1.06, which implies that the crop production system scored increasing returns to scale. The OLS estimates indicated that food consumption was positively influenced by the age and the marital status of the household head, the household size, farm income, land size, crop production, when bean, maize, potato, rice and soybean were the main crops selected by the farmers, while it was negatively affected by the sex of the household head, when coffee and wheat were the crops chosen by the farmers. The results from Pearson's correlation analysis showed that food consumption was positively and significantly (p=0.00) correlated with family size, farm income, land size, and crop production. With reference to these findings, we recommend that the strategies to increase the crop yield and farm income and thus sustain food consumption and improve farmers' welfare should be enhanced.

Keywords: *crop yield, farm income, food consumption, farmers' welfare, Rwanda*.

Introduction

Crop production should be a primary source of rural development and a cornerstone of farmers' livelihood through the increased yield (Gollin et al., 2002) specifically in less developed economies (Jalan & Ravallion, 2002). It is expected to be a profitable enterprise for it to provide enough income to crop growers (Pender et al., 2004; Maniriho & Bizoza, 2013) and thus to contribute to positive transformation of farmers' welfare (Nyambose & Jumbe, 2013). However, the available resources (mainly land and labour) are not used for high productivity, and this constrains the agriculture to assume appropriately its role in economic development of mainly availing enough food to the population of a country and providing the surplus for exports (Johnston & Mellor, 1961).
In intent to move farmers to the improved level of livelihood, the Government of Rwanda has initiated different anti-poverty programs. As far as the agriculture sector is concerned, the Crop Intensification Program (CIP) was launched in September 2009 to modernise agriculture (MINECOFIN, 2012; Alinda & Abbott, 2012), complemented with "one cow per poor family program" whose main role was to enable the poor to access to protein, and to supply them sustainable organic fertilizers (Kato et al., 2011; Nilsson et al., 2019) that are important for erosion reduction, food security and climate change adaptation (Lal, 2004). Throughout the Economic Development and Poverty Reduction Strategy (EDPRS), agriculture is considered as cornerstone driver for long-term growth and appeals for public efforts in conjunction with

all other development partners to stimulate increasing use of improved inputs and to encourage them to participate in both implementation and monitoring (Government of Rwanda, 2007). Further, the National Decentralized Policy integrates agriculture development in the planning and management of the holistic development process by taking it as the priority area and empowering local populations for them to participate in the initiatives aiming at graduating them out of poverty (Bingen and Munyankusi, 2002).
Previous studies reported the positive effects of some socioeconomic development initiatives on household welfare in Rwanda. With reference to CIP, Maniriho and Bizoza (2013) showed that potato, wheat, maize, tomato, onion, and cabbage are profitable crops that are more likely to improve the farmer's welfare, including nutrition. For one cow per poor family program, Nilsson et al. (2019) found out that the program affected positively the crop production but not the per capita consumption.

Table 1. Comparison of potential yield to current yield of selected CIP crops in Rwanda.

No	Crop	Potential yield (Tones/ha)	Current yield (Tones/ha)	Gap (Tones/ha)
1	Maize	3.79	1.53	2.26
2	Bean	1.60	0.91	0.69
3	Rice	6.69	3.40	3.29
4	Wheat	3.17	1.33	1.84
5	Cassava	38.89	13.54	25.35
6	Potato	20	8.65	11.35
7	Soybean	2.25	0.51	1.74

Note: The information on the potential crop yields are obtained from the technical factsheets published by AFSR (*Appui à la Filière Semencière au Rwanda*) in 2007. The average for different varieties was computed except for the potato where the minimum is considered (the potato average potential crop yield is 29.69 Tones/ha). As for the current crop yield, we considered the statistics of Seasonal Agricultural Survey data, season 2018A, published by National Institute of Statistics of Rwanda. Further, CIP stands for Crop Intensification Program in Rwanda, and ha for hectare.

The current statistics show that the agriculture sector increased at the growth rate of 6% in 2018, while the whole economy increased at 8.6% (NISR, 2018a). Notwithstanding all these efforts and the agriculture development achievements, the malnutrition issues are still crucial among Rwandans especially the stunting cases (World Bank Group, 2018) at the countrywide rate of 35% (NISR, 2018b).
The purpose of this study is to assess the prospects of crop production and food consumption for farmers' welfare. It aims specifically to analyze the relationship between the crop choice and the welfare categories, to compare the mean food consumptions between the growers and non-growers of selected crops, and identify the determinants of crop production and factors influencing food consumption in Rwanda.

Materials and Methods

This study used secondary data collected through the Fifth Integrated Household Living Conditions (EICV 5) survey from October 2016 to October 2017. This is a national level survey conducted on a random sample of 14 580 households, sampled from 245 villages and 2 526 households in urban areas and 1 015 villages and 12 054 households in rural areas. It contained 10 cycles on the whole year to account for seasonality of household incomes and expenditures. Part of the purpose of EICV5 was to avail required statistics to enable the assessment of the anti-poverty initiatives undertaken by the Government of Rwanda (NISR, 2018b). The study variables are well described in Table 2.

Table 2. Descriptive Statistics of the study variables.

Variable	Obs	Mean	Std. Dev.	Min	Max
Age (years)	11801	46.94	15.58	14	105
Mar_status (1=married)	11801	.91	.28	0	1
Sex (1=female)	11801	.26	.44	0	1
Family size	11801	4.58	2.04	1	17
Production (FRW)	11801	393.13	1,250.81	1	58,000
Agri_income (FRW)	11801	5,515.69	47,371.66	0	2,730,000
Food cons. (FRW)	11801	742,000	513,000	8138.57	6,210,000
Land size (ares)	11801	58.64	256.47	.02	13,476
Labour (FRW)	11204	14,365.22	54,472.83	0	1,400,000
Chemical fertilizers (FRW)	11204	5,362.99	31,962.01	0	2,700,000
Organic fertilizers (FRW)	11204	1,590.95	10,888.66	0	575,000
Pesticides (FRW)	11204	1,774.81	14,120.99	0	700,000
Traditional seeds (FRW)	11204	6,312.17	17,169.83	0	700,000
Improved seeds (FRW)	11204	2,247.89	19,699.16	0	1,000,000
Poverty*	11801	2.50	.73	1	3

Note: * indicates that poverty is measuring the welfare categories (1=severely poor, 2=moderately poor, and 3=non poor). FRW stands for Rwandan francs. Food cons. means food consumption, and Mar_status stands for marital status.

For analyzing data, the Chi Square statistic was computed to test for the association between two categorical variables (Diener-West, 2008) using the formula 1.

(1) $\chi^2 = \sum \frac{(O-E)^2}{E}$,

Where χ^2 is the Chi Square statistic, O stands for the observed frequency, and E the expected frequency.

To test for the association between continuous variables, the Pearson Product-Moment Correlation coefficient "r_{xy}" was computed (Asuero et al., 2006; Hall, 2015). This is known as the ratio of the normalized covariance of two continuous variables "C_{xy}" to the square root of their variances "$\sqrt{C_{xx}C_{yy}}$", and well described by the formula 2. The pairwise correlations between food consumption, crop production, land size, farm income, family size and the age of the household head were computed.

(2)
$$r_{xy} = \frac{\sum_i (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_i \{[(x_i - x)^2][(y_i - y)^2]\}}} = \frac{C_{xy}}{\sqrt{C_{xx}C_{yy}}} = \frac{C_{xy}}{\sigma_x \sigma_y}$$

The third method used to analyze data is the t test. The t statistic was used to compare food consumption between producers and non-producers of selected crops (maize, potato, bean, soybean, wheat, coffee and rice). The t statistic was computed using the formula 3.

(3) $t = \frac{M_1 - M_2}{\frac{S_1}{\sqrt{n_1}} + \frac{S_2}{\sqrt{n_2}}}$

Where $(M_1 - M_2)$ is the difference between the means of the two groups (the growers, and the non-growers of selected crops), S_1 and n_1 are the standard deviation and the size of one group, S_2 and n_2 are the standard deviation and the size of another group, respectively.

Finally, an econometric approach was used to identify the factors affecting crop production and food consumption among crop growers. Following Gujarati (2009) and Wooldridge (2013), the model to be estimated for this case study is described by the formula (4).

$$(4)\, Y_i = \beta_0 + \beta_2 \sum_{k=1}^{n} X_{ki} + e_i$$

where Y is a dependent variable (food consumption, or crop production), Xs are independent variables, e_i is a disturbance term, βs are parameters to be estimated. For identifying the determinants of crop production, two models were specified and estimated. One is the linear model that included both farm inputs and socioeconomic characteristics of farmers (following the application by Mpawenimana, 2005 as an example), while the other is a Cobb-Douglas production function that included exclusively the farm inputs (see Debertin, 2012 for details). As for the food consumption function, a linear model was chosen (see Gujarati, 2009). Seeing that crop production was among the determinants of food consumption, a Two-Stage Least Squares (2SLS) estimator was used to estimate the coefficients of this function and to account for endogeneity and simultaneity bias (Wooldridge, 2013).

Results and Discussion

This study attempted to compare the average food consumption between producers and non-producers of main crops grown in Rwanda, namely maize, potato, bean, soybean, wheat, coffee and rice. The results from the t test show that crops whose producers consume more food than the non-producers are the maize, potato, bean, soybean and rice, while the producers of wheat and coffee afford less food than the non-producers (see Table 3).

This could be due to the fact that the production system of coffee and wheat requires the farmers to incur huge amount of expenses, which appeals the household members to deprive themselves from some food items for sometimes. The table 4 summarizes the relationships between different crops and welfare categories. The results show the percentages of the crop producers who are severely poor, moderately poor and non-poor, respectively. For the maize for example, 11.01% of producers are severely poor, 20.64% are moderately poor, while 68.35% are not poor. The first three crops with high percentage of non-poor are rice, maize and soybean, with 72.43%, 68.35% and 67.49%, respectively. The Chi-square test (formula 1) indicates that the welfare of Table 3. Comparison of food consumption between producers and non-producers of different crops.

households is significantly associated with maize production (chi2=164.40; p-value=0.00), bean production (chi2=103.72; p-value=0.00), and potato (chi2=83.35; p-value=0.00), as well as soybean and rice. However, wheat (chi2=4.28; p-value=0.12) and coffee (chi2=0.57; p-value=0.75) are not significantly associated with household's welfare.

Table 4. Relationships between different crops and welfare categories.

Welfare categories	**Maize growers**	**Potato growers**	**Bean growers**	**Soybean growers**	**Wheat growers**	**Coffee growers**	**Rice growers**
Severely poor (%)	11.01	11.74	13.13	11.30	14.49	13.38	7.79
Moderately poor (%)	20.64	21.18	22.22	21.21	25.62	22.87	19.77

This enhances the idea that farmers should choose to grow the crops that contribute to the improvement of household welfare (Pender et al., 2004; Maniriho & Bizoza, 2013; Nyambose & Jumbe, 2013). This shows the positive effects of the crops selected for the implementation of the Crop Intensification Program (CIP) to the transformation of livelihoods in Rwanda, even though the issue of low productivity of these crops remains crucial (Table 1).
Concerning the econometric analysis (Table 5), the 2SLS estimates from Model 1 indicated that food consumption was positively influenced by the age and the marital status of the household head, as well as the household size, , while it was negatively affected by the sex of the household head. For the crop production, the log-log model (R2=0.39) was superior to the linear model (R2=0.36). The results revealed that the crop output increased with the increase in inputs (labour, chemical fertilizers, organic fertilizers, pesticides, and traditional seeds) in line with the existing literature in economics (Dwivedi, 2006; Schotter, 2009; Besanko et al., 2011; Debertin, 2012). The effect of improved seeds on crop production was unexpectedly negative. This could be due to the seeds and/or the farming practices that may not be adapted to the soils, or to climate variability. The results also show that the crop system uses intensively the organic fertilizers (given their elasticity of 0.38) followed by labour (elasticity=0.21). This implied that the use of chemical fertilizers should be enhanced if the increasing crop productivity is to be achieved. The table 5 shows the pairwise correlations of the key variables of the study, and table 6 summarizes the linear regression estimates of food consumption and crop production.

Table 5. Pairwise correlations of the continuous variables.

--	--	Farm income	-0.001***	--	--
--	--	Crops dummies	Yes [b]	--	--
--	--	Locat. factors	Yes [c]	Return to scale	1.06 [e]
Constant	165000.00***	Constant	-104.41***	Constant	1.66***
Obs.	11801	Obs.	11204	Obs.	148
R-squared	0.028	F-stat	23.86	F-stat	20.697
Chi2	2993.35	Prob > F	0.00	Prob > F	0.00
Prob > chi2	0.00	R-squared	0.35 [d]	R-squared	0.509 [d]

Note: *** p<0.01, ** p<0.05, * p<0.1. [a] Crop production was instrumented with land size, farm income, chemical and organic fertilizers, traditional and improved seeds, as well as pesticides. [b] Crop dummies (yes=1; selected crops: maize, bean, soybean, rice, wheat, potato, and coffee). [c] This study controlled the location by including province, district and clusts (villages) in the regression. [d] The R-square was significant as the study used cross-section data (see Wooldridge, 2002 for details). [e] The return to scale of 1.06 implied that the crop farming scored increasing returns to scale (see Debertin 2012 for details). Ln stands for natural logarithm, hhsize for household size, mar_status for marital status, chem. fert. for chemical fertilizers, org. fertil. for organic fertilizers, crop prod for crop production, tradit. for traditional, improve. for improved, and locat. lor locational (factors).

Besides, the return to scale of crop production was 1.06, which implied that the farming system scored increasing returns to scale. This means that the crop output increased more quickly than the inputs increase (Dwivedi, 2006; Schotter, 2009; Besanko et al., 2011; Debertin, 2012). The regression estimates were complemented with the pairwise correlations of continuous variables given in Table 6. These results showed that food consumption was positively and significantly correlated with farm income, land size, crop production and family size. As for the crop production, the results indicated that it was positively and significantly correlated with land size, farm income, family size and food consumption.

Conclusion and Recommendations

This study attempted to assess the way farmers' welfare is affected by crop production and food consumption in Rwanda. In collaboration with diverse development partners, the Government of Rwanda committed to boost crop yield so as to increase farm income and improve farmers' welfare. We used the 5th round of the Integrated household life conditions survey data collected from October 2016 to October 2017. The Chi-Square test, the Pearson's correlation coefficient, the t test, and the OLS methods were used for data analysis.
The results from linear regression analysis showed that the increase in agricultural inputs lead to a significant increase in crop output with increasing return to scale. The t test showed that the crop farmers who grew maize, potato, bean, soybean and rice had higher consumption than the producers of other crops (see Table 2). Besides, the chi-square test outcome indicated that the production of maize, potato, bean, soybean and rice were significantly associated with the welfare categories (see Table 3). The results of both t and chi-square tests implied that the production of maize, potato, bean, soybean and rice made the farmers better off than other crops. As for the correlation test (see Table 6), the results showed that food consumption was positively and significantly correlated with family size, farm income, and land size, but not significantly correlated with crop production. This complemented the positive effects of these variables on food consumption as revealed by 2SLS estimates of the Model 1.
From the OLS estimates of the Model 3, we concluded that the crop output was driven by the amount of labour, fertilizers, pesticides and seeds used. The most influential inputs were organic fertilizers, labour and pesticides and the agriculture scored increasing returns to scale. The results from econometric estimations and other statistical tests led to state that crop production was among the primary drivers of famers' welfare besides the farm income, the land size and the family size.
With reference to these findings, we recommend that the strategies to increase the crop yield and farm income and thus sustain food consumption and improve farmers' welfare should be enhanced.

Abstract

Monitoring and Evaluation in Agricultural Advisory Service provide the basis for organized learning from experience according the reliable information collected during and after the implementation of advisory programs. These processes allow improvement of the provision of services, responsible resource allocation as well as planning of advisory programs in accordance with agricultural policy as well as the needs of agricultural producers. The objective of the research is to determine the existing situation regarding monitoring and evaluation system. Research has been implemented on two levels. The first part of research is on the level of the Public Advisory Service of Republic of Srpska while the second part of the research has been conducted at the level of institutions and organizations that are partners of Public Advisory Service. Based on empirical research and data from different sources the goal is to create basic elements of monitoring and evaluation in agricultural advisory services that can be used in practice by employees in the Public Advisory Service of Republic of Srpska. Based on the analysis of the situation and the results of the research, it is concluded that for the implementation of the monitoring and evaluation process the most important commitment of the management of the public agricultural advisory service is to collect and analyse the data. It is also necessary to improve the human, material and technical capacities within the advisory service and also ensure the development of information systems as well as special resources, both human and material, for the implementation of monitoring and evaluation.

Keywords: *Monitoring and evaluation, Agricultural Advisory Service, Republic of Srpska.*

Introduction

To improve and optimise contribution of extension service to rural livelihoods it is essential to monitor and evaluate its achievements. High quality monitoring and evaluation based on reliable information about the outcomes and impacts of services are a foundation for structured learning from experience. Monitoring and evaluation are also essential to ensure that those supporting and undertaking interventions to improve advisory services are accountable to the direct clients of these services as well as to governments, farmer organisations, and others investing in improving extension service (Christopolos *et al*., 2012). The Global Consultation on Agricultural Extension observed that monitoring and evaluation are important yet frequently neglected functions in most organizations (FAO, 1990, p. 27). In the worldwide survey of national extension systems, it was found that only about one half of all national extension systems have some type of monitoring and evaluation (M & E) capacity. The consultation noted that in many cases the M & E units are weak and are limited to ad hoc studies. Frequently, these M & E units are abandoned when project funding terminates. In many organizations, monitoring and evaluation have a negative image because these units may concentrate on problems, exposing weaknesses and failures. Instead, monitoring and evaluation should be used in a positive manner to improve extension's performance and increase its efficiency.[9] In December 2014, the United Nations General Assembly adopted a Resolution entitled "Building capacity for the evaluation of development activities at the country level" (UNGA Resolution A/RES/69/237). Through this Resolution, member states agreed that evaluation was an important component of developmental processes and recognized national-level evaluation as a tool to help strengthen and support to developmental results.

Monitoring and evaluation (M&E) of development activities provides government officials, development managers, and civil society with better means for learning from past experience, improving service delivery, planning and allocating resources, and demonstrating results as part of accountability to key stakeholders.[10] Monitoring and evaluation can help organization extract relevant information from past and on-going activities that can be used as the basis for programmatic fine-tuning, reorientation and future planning. Without effective planning, monitoring and evaluation, it would be impossible to judge if work is going in the right direction, whether progress and success can be claimed, and how future efforts might be improved.[11]

Monitoring and evaluation in the world are a regular activity in implementing public policies, projects and programs to ensure responsible use of resources and achieving measurable and sustainable results. The Public Agricultural Advisory Service in the Republic of Srpska operates within Department for agriculture advisory service which is one of the five departments within the organizational structure of the Ministry of Agriculture, Forestry and Water Management of Republic of Srpska. This Department conducts its activities in the territory of 64 municipalities in Republika Srpska through the seven regional units and one coordinating office. There are 33 advisors employed in these regional units. The fact that 42377 agricultural farms were registered in Republic of Srpska in 2018 suggests is that all agricultural producers can not have a high quality access to advisory services, primarily because one advisor should oversee 1284 agricultural farms. Creating an appropriate information system for the recording of advisory work, needs of agricultural producers and the basic elements of the monitoring and evaluation plan or report, it is possible to collect information in a standardize and systematic way for the objective reviewed of the advisory work and to create the basis for lesson learned, improved personal and collective accountability.

Considering the limited human and material capacities of the Public for agricultural Advisory Service of the Republic of Srpska, the selection of the topic and the purpose of the present paper is to provide an overview for possibilities of achieved rational use of resources, and improved existing mode of work.

Material and Methods

The paper is based on an review of primary data collected by structured questionnaires carried out in 2018 and on empirical research and data from different sources. Primary data have been collected with two online survey questionnaires. These surveys provided information on the existing status in the area of advisory activities/services, and then on the relationship between advisors and partners who are in direct or indirect cooperation with the Public Agricultural Advisory Service of Republic of Srpska according to the monitoring and evaluation system. The first questionnaire was created for obtaining primary data from advisors who are

employed in Public Agricultural Advisory Service of Republika Srpska. The questionnaire contained 25 closed-type questions aimed at identifying the existing situation regarding the records of advisory activities, then the relationship of advisors to the monitoring and evaluation system, and knowledge of the role and importance of monitoring and evaluation in advisory service. Second questionnaire contained 20 closed-type questions. Questionnaire was created for institutions and organizations that are in direct or indirect cooperation with Public Agriculture Advisory Service. The aim was to identify the importance and the role of the advisory service partners in the planning and implementation of advisory activities as well as the relation of the partners to the monitoring and evaluation process as well as the knowledge of the role of monitoring and evaluation in the planning process. The most responses were received by agricultural cooperatives (23%), then non-governmental sector (20%) and agricultural associations (17%). Also, the representatives of academic institutions (7%) and administrative bodies and organizations (13% and 3%), the local community (10%) and the private sector (7%) were interviewed. In addition to the questions specific to a particular group of respondents, several identical questions were defined in two questionnaires, in order to compare the attitudes of both groups of respondents. The comparison was made with regard to the attitudes of the respondents regarding the meaning of the monitoring and evaluation, the conduct and manner of keeping records of the activities carried out, the purpose of monitoring and evaluation, the importance of participation of individual actors in the monitoring and evaluation process, and the attitudes of respondents regarding education in the field of monitoring and evaluation .

Based on empirical research and data from different sources the optimal model of the monitoring and evaluation plan and reports were created.

Results and Discussion

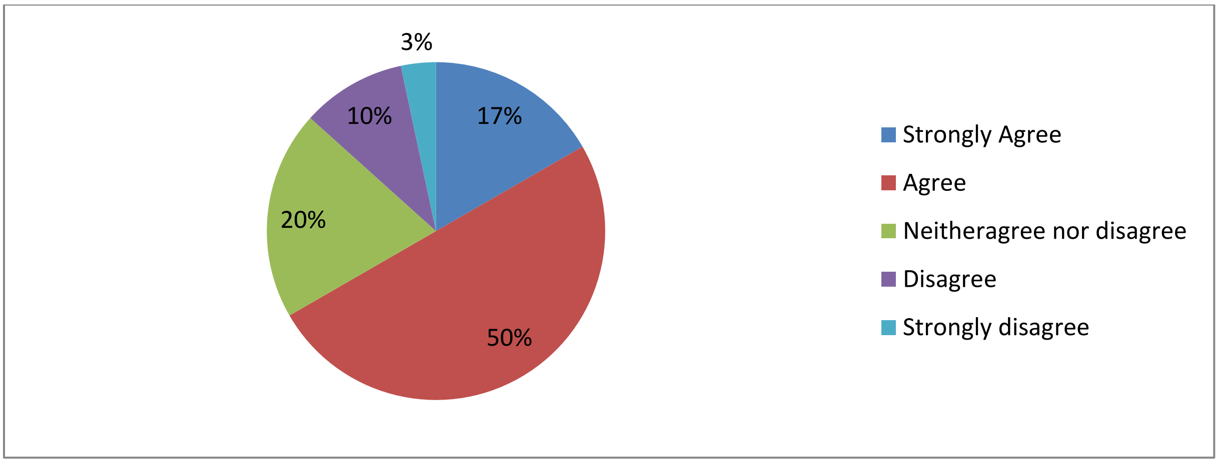
Obtained data provide insight into the importance and role of partners of public agricultural advisory services in the planning and implementation of advisory activities and process of monitoring and evaluation. Of the total number of surveyed partners, 90% are engaged in an institution/organization that cooperates with the Public Agricultural Advisory Service of Republic of Srpska. The analysis shows that 63% of the total number of respondents are beneficiaries of advisory services and 67% of them participated in the creation and implementation of advisory programs / projects / activities in cooperation with the Public Agricultural Advisory Service of the Republic of Srpska. The largest number of respondents (advisors and partners), 56% of them believe that the term monitoring refers to monitor the implementation of activities while 40% of them believe that the evaluation is a term describing the assessment of someone or something according to the established criteria. Most of respondents (70%) keep records of the activities that are being carried out, and activities are recorded in the planner/note books (41%) and in MS Word (30%).

Table 8 Methods of recording activities

Answers	Frequency of answers			Part %
	Advisors	Partners	Total	
MS Word	13	18	31	30
MS Excel	7	10	17	16
Planner/Notebook	23	20	43	41
System for recording activities	3	10	13	13

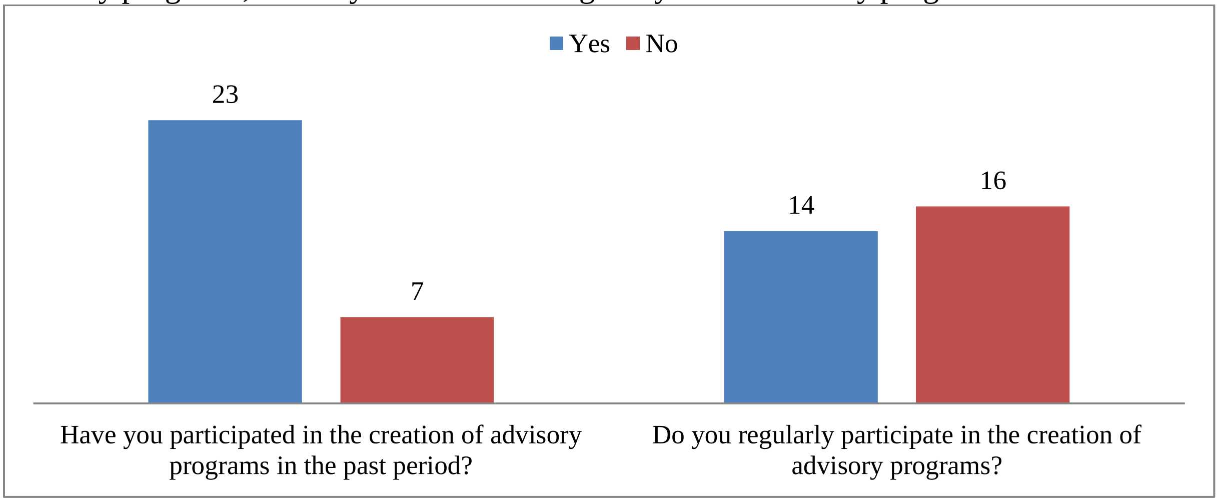
Most advisors (53%) believe that the existing record method only partially provides a clear overview and planning of future activities, and 40% of them believe that the existing method of evidence is quite appropriate.

Most advisors (60%) have had an insight into the opinion of agricultural producers on the basis of oral conversation with agricultural producers and 24% of them base their insight in producer's problems on their own estimates. Both groups of respondents agree that the purpose of monitoring and evaluation is to assess whether the activities are implemented according to plan, establish the value and importance of the specific activity, and helps to improve work with conclusions, lessons learned and recommendations and to allow the rational use of human and material resources. There is a significant degree of interest of the respondents (92%) for participation in trainings on monitoring and evaluation and in order to improve work in the future. Respondents believe that the greatest significance in the process of conducting monitoring and evaluation should have the management, employees and service beneficiaries while the least importance in the context of these processes should have external and internal evaluators. Claim that under the advisory services process of monitoring and evaluation should address to special unit which will dispose of the special human and material resources supports 67% of the advisors, 20% have a neutral attitude, while 13% disagree with the statement.



Graph 1. Attitudes about the existence of special unit for monitoring and evaluation

The largest number of advisors (64%) organizes their work within pre-defined advisory programs while 97% of institutions/organizations organize their work within pre-defined projects / programs. In the previous period 77% advisors participated in the creation of advisory programs, but only 47% advisors regularly create advisory programs.



Graph 2. The situation in the field of creating advisory programs

The monitoring process is carried out by 87% and the evaluation process is carried out by 77% surveyed institutions/organizations.
Based on the survey results and insight into the existing situation, activities within the public agriculture advisory services are planned according to the needs of agricultural producers without setting target values, results and impacts. When planning advisory programs, it is necessary to analyse the situation at first in order for these programs to respond to the needs of the target group and at the same time to enable agriculture policy to be implemented. The monitoring and evaluation process itself begins with the already conceived data collection system by pre-designing and determining the target values and impacts of the advisory programs. In order to create advisory programs and then monitor and evaluate these programs it is necessary to have defined basic elements of the logical framework. The basic elements of the logical framework of advisory programs are necessary to show the link between investment, activity, services (outputs) and effects, i.e. desired results or changes at individual and collective level. Based on the presented logical framework it is evident that monitoring mainly focused on investments, activities and results while evaluation is focused on outputs of programs.

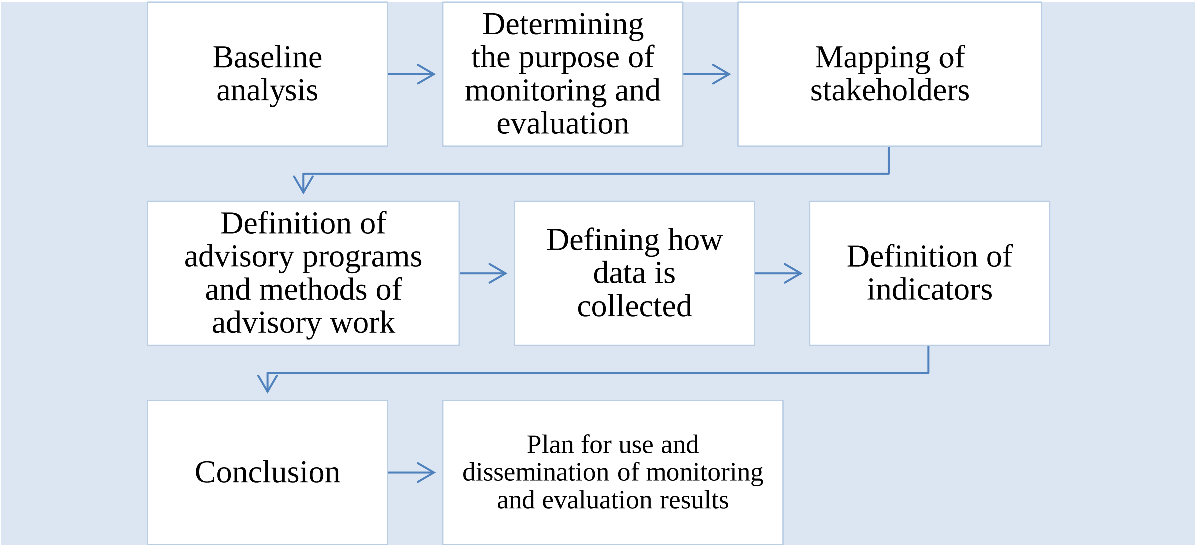
Table 9. Logical framework for monitoring and evaluation process in advisory service.[12]

Monitoring			Evaluation		
Inputs	Outcomes		Outputs		
Investments	Activities	Participation	Short Term	Medium Term	Long Term
What we invest?	What we do?	Who we reach?	What the medium term results are?	What the medium term results are?	What is ultimate impact(s)?
Staff; Volunteers; Time; Money; Equipment; Technology; Partners.	Conduct workshops, meetings; Training; Provide advisory; Work with mass media; Making field trials; organization of events;	Individual agricultural producers; Organized agricultural producers; Decision makers;	Learning: Awareness; Knowledge; Attitudes; Skills; Opinions; Aspirations; Motivation.	Action: Behaviour: Independence in work, application of new techniques and technology.	Conditions: Social; Economic; Environment.

Based on the research, the optimum model of the monitoring and evaluation plan is created. The model envisages a several steps in creation of an optimum MiE plan: first is a definition of the purpose of monitoring and evaluation, which then determines the stakeholders, the second is to define advisory program and advisory methods that will be used in the implementation of the program, the third is definition of the methods of collecting data as

[12] Adapted from: https://articles.extension.org/pages/70478/logic-models:-a-tool-for-program-planning-and-assessment

well as indicators and methods that will be used for their analysis and the person responsible for analysing and drawing conclusions. The final stage of this plan defines the plan for using the results.



Scheme 1. Proposal of model for monitoring and evaluation plan in agriculture advisory service[13]

The final monitoring and evaluation report is a written document that describes how the advisory program is monitored and evaluated. It presents the results, conclusions and recommendations of the monitoring and evaluation. The monitoring and evaluation report describes the advisory program, its purpose and advisory activities aimed at the implementation of the advisory programs. This report provides an answer as to whether the program is implemented in accordance with the plan and whether the changes that have been made are in accordance with the purpose of the program. The purpose of the report is to provide recommendations and conclusions to the management, advisers and other interested parties on how to improve future advisory programs or justify implementation, interruption or adjustment of advisory program to the current situation.

Conclusion

The monitoring and evaluation activities are a regular practice in implementation of public or development policies, that allows to determine the relevance, effectiveness and efficiency of such politics, projects and programs. Monitoring and evaluation serve to provide feedback as to whether advisory activities are related to the needs of the beneficiaries, whether satisfactory performance is achieved, and whether certain activities can be organized and implemented by other methods in a more efficient way.
Based on the research, it is noted that public agricultural activities carried out in Republic Srpska are performed using planner/notebooks and MS Word tools. Most advisors believe that the existing method of records allows a clear overview and planning of future activities, need assessment is performed via oral discussions with farmers and based on personal observation. Hense, there is a need to implement MiE system as integral part of Agriculture Advisory Service activities in order to obtain timely information for decision-making, planning of human and material resources and improving the provision of advisory services. Such a system should also alow measurement of a short-term, mid-term and long-term results of

[13] *Source: Author's elaboration based on the survey results.

implemented advisory activities. The MiE system should consist of an monitoring and evaluation plan and MiE report.

For the implementation of monitoring and evaluation system within Public Advisory Service it is necessary to have a commitment of management of advisory service to establish a special department in charge of monitoring and evaluation and to provide regular support to persons responsible for the management and maintenance of computer systems and networks. Insufficient numbers of human and material resources are also a limiting factor for the implementation of these processes.

Therefore, it can be concluded that the needs for monitoring and evaluation tools will became evident with the development of advisory service in the future in order to analyse the target groups and their needs, methods of advisory work and allocation of resources, all in order to improve efectivness of the advisory services on production productivity and economic benefits of the beneficiaries.

Abstract

Demands for quantity, quality and diversity of food products have never been higher. Satisfying consumers’ fast-changing demands and high expectation regarding food-related products is a big challenge for food producers and agriculture industry. Response to this challenge can be seen in smart and sustainable agriculture. Novel Information and Communication Technologies (ICTs) have brought immense improvements in a wide scope of domains and agriculture didn’t remain immune to the progress of modern technologies. The increased production and enhanced farming practices with the reduced negative influence on the environment and sustainable utilization of resources are some of the characteristics of agri-food industry of the 21st Century. However, the overall success of the agri-food sector is not possible without adequate marketing practices that will make a strong bond between food producers and consumers. The purpose of the paper is to examine the role and opportunities of ICTs use in agricultural marketing, and the significance of effective agricultural marketing in business development. The particular attention has been devoted to the digital marketing strategies applicable in agriculture and the benefits they bring. The presented research shows that the symbiosis of modern ICTs and marketing strategies in agriculture transformation will increase the satisfaction and loyalty of current customers, gain more customers, and boost sales and profits.

Keywords: *ICT, agriculture, marketing, customer.*

Introduction

With the increasing worldwide population, assuring required quantities of safe, quality, and affordable food is a key challenge of modern society. In order to achieve this goal, food processors and distributors work intensively to find novel methods for increasing the production and achieving sustainable agriculture and food industry (Maksimović et al., 2019). The novel Information and Communication Technologies (ICTs) have already transformed agriculture and food industry, through each phase of the agri-food supply chain (food production, packaging, processing, transportation, distribution, preparation, and marketing). Production automation, precision farming practices, remote and real-time monitoring and controlling, traceability, decision making, and forecasting, are some of the improvements brought by modern ICTs in the agri-food sector, that promise to make agriculture and food industry smarter and more sustainable than ever before.

In the 21st Century, agri-food industry sector has become consumer-centric and established on fast-changing consumers’ demands in the sense of diversity, quality, and quantity of food products (Maksimović et al., 2019). At the same time, the success of food producers and food products depends on food production and marketing system between agricultural producers and consumers (Islam, 2011). Agriculture and marketing strategies together have created a term “agricultural marketing” that involves all activities in the movement of agricultural inputs and products from the farms to the final consumers, and the effects of such activities on all players in the food supply chain (Ul-Rehman, et al., 2012). Marketing in the agri-food sector must be customer-oriented, hence providing all participants in the food supply chain with profit and satisfaction.

This paper presents an attempt to summarize the significance of novel ICTs and marketing strategies in realizing the smart and sustainable agri-food sector, that will substantially provide significant economic and social benefits. There is no doubt that technological innovations and marketing system improvement are key components for agricultural development.

The influence of ICTs on agriculture practices and marketing strategies

Technological achievements in recent years (sensors, robots, smartphones, automatic control, Cloud and Fog services, Wireless Sensor Networks (WSNs), Internet of Things (IoT), nanotechnology and many other emerging technologies) have completely revolutionized agri-food industry (Maksimović et al., 2019). The main benefits brought by novel ICTs in agriculture are: the automation of production, better management of cultivation factors, more efficient utilization of agrochemicals and water, precise, productive and sustainable farming practices, logistics, traceability, real-time and remote monitoring, decision making, forecasts, etc., therefore contributing to the fulfilment of the growing food requirements. Moving towards green technologies, environmental and human safety has been increased.

The IoT implementation in the agri-food sector enables the remote monitoring and real-time access to massive amounts of heterogeneous data collected from the farm to fork. A huge number of sensor nodes deployed throughout the entire food supply chain enable numerous real-time information related to food production, processing, transportation, and storage. These data must be gathered, processed and analyzed in a proper manner so that they can be useful for making predictions and decision making. Having the right information at the right time enable fast and timely reaction, associated to soil improvements, plant and animal breeding, agrochemicals control, disease diagnostic, food packaging, traceability, food safety, hence avoiding potential food contamination, spoilage, foodborne diseases, and increasing production, profit, energy and resource efficiency, and environmental protection. In other words, knowledge extraction and smart decisions lead to the realization of smart, efficient and sustainable agriculture and food sector.

Alongside the development of the agri-food sector influenced by novel technologies, the marketing system has also changed. IoT inclusion in marketing domain enables the constant company-customer connection, monitoring, analysis and prediction of consumer behaviour, delivery of personalized and targeted messages, products or services to customers, customers greater involvement, as well as automated loan eligibility computation, access to latest inventory data of agro inputs, logistics and storage service providers, provision of the up to date market information through the digital connection to the online domestic and international market place (Fig. 1) (JMR AgriNet, n.d.; Gavrilović and Maksimović, 2019). All these activities lead to a higher level of company and customer satisfaction.

Technology-driven marketing strategies play a key role in the production and consumption stimulation in agriculture and economic development. However, agricultural marketing should be considered as unique due to perishability and bulkiness of the food products. As such, agricultural marketing deserves special attention.

Figure 1. Connected agro-digital platform (JMR AgriNet, n.d.)

Agricultural marketing

The entire organization, as well as the entire marketing system, must adopt the marketing concept. An agricultural and food marketing system consists of interconnected sub-systems that are autonomous of one another, but which possess a defined common goal and perform actions necessary to profitably exploit opportunities in the marketplace (Crawford, 1997). Agricultural marketing consists of two major concepts:

- agriculture - producing agri-food products using natural factors, and
- marketing – business organization activities aimed to promote products and services to targeted customers.

Agricultural marketing is mainly defined as the complex of activities involved in the supply of farm inputs to the farmers and the flow of agri-food products from the farm producers to the consumers. Agricultural marketing system encompasses (Luanar, 2017):

- assessment of the requirement for farm-inputs and their provision,
- post-harvest treatment of farm products,
- execution of various actions needed in transferring farm products from the farm to processing industries and/or to end consumers,
- assessment of demand for farm products and public policies and plans pertaining to the pricing,
- handling, purchase, and sale of farm inputs and agricultural products and increasing the farmer profit.

Achieving maximum sales and profit requires an effective and profitable agriculture marketing plan. Development of such a marketing plan includes the following steps (Fig. 2) (Garcia, 2017):

- understanding the customers' needs and identifying the potential customers,
- offering something different and unique to customers,
- formation of experienced professionals' teams for each segment of the agriculture business,
- choosing the right advertising techniques,
- evaluation of implemented marketing techniques.

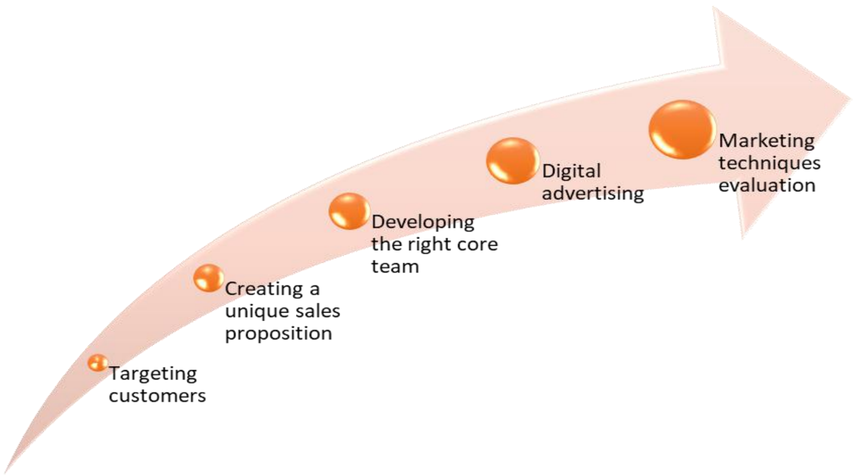

Figure 2. Marketing plan steps

Agricultural marketing is crucial for production and consumption stimulation, delivery of agri-food products in time, at the right place, in proper form and reasonable price. It also plays an immense role in agricultural and economic development through the optimization of resource usage and output management, farm profit increase, markets' widening, agro-based industries growth, price signals, inclusion and implementation of novel technologies, employment creation, addition to national income, improved living, creation-, form-, place-, time- and possession utilities (Luanar, 2017). The most substantial influence on the success of the agri-food sector have customers that can be attracted and maintained through the improved customer services and satisfaction and increased engagement. Prerequisites for achieving these goals are effective market surveys, market trending and continuous follow up (Kiruthiga et al., 2015).

Digital marketing strategies for agriculture

Nowadays, traditional agricultural marketing strategies are not adequate for modern society in which people are constantly connected to the web through smartphones, tablets, and computers. In order to extend to these viewers, traditional agribusiness marketing practices have evolved to the digital agribusiness marketing practices (Fig. 3) in which Internet is a most effective mean for the promotion of products and the provision of information.

Creating a name, symbol or design in agribusiness refers to a marketing branding practice which aim is to identify and differentiate an agri-food product from other similar products. Having a strong and internationally recognized brand is crucial for the success of any agri-food business.

The farmer and any agri-food related organization in digital marketing must have optimized and up to date website that will adopt the best practices of search engine optimization (SEO). On this way, the most interested users will be targeted and moved to these websites. The realization of such websites requires intensive work on certain tasks such as (WebFX, n.d.):

- The definition of title tags and keywords - a concise description of what can be found on a page enables users to move easily and faster, therefore finding easily what they are looking for.
- Posting blogs – regularly writing posts focused on readers keep visitors coming back to the website. Both short and long posts give impressions of serious business organizations and assist in building a better relationship with potential customers.
- The usage of graphics, images, and videos– visualizations related to the business attracts more visitors, make them stay longer on the website and potentially convert them to the customers.

- The usage of search engine marketing (SEM) –is the most effective way to grow the business and reach new customers. Using SEM for marketing and advertising enables more visits to websites and better brand recognition.

Figure 3. Digital marketing strategies (Shastri, 2017)

In the era of social networks, it is almost impossible that farmers or agriculture company's online strategy is not based on the popular social media platforms such as Facebook, Twitter, Pinterest, LinkedIn, and other platforms that are extremely effective for marketing purposes. Social media in agricultural marketing enables saving time and costs for getting information and is the most comfortable way for the farmers and companies to reach current and potential customers.

Email marketing is one of the best strategies to send the right information at the right time to current and potential customers. Sending the novel information and offers increases the brand awareness, remind customers of the business, and keep shoppers coming back for more.

Content marketing is one of the most powerful digital marketing strategies that is focused on the creation and distribution of timely, relevant and valuable content to current and potential customers in order to influence their behavior. In the agriculture industry, content marketing plays an immense role as it gives customers quality and valuable content and directly influences customer loyalty, what at the end lead to an increase in the company's revenue.

Mobile marketing services also play an important role in the agricultural business as they enable the instant connection with clients and customers (i.e. sending novel information, promotions and offers via SMS messages) without the participation of a middleman, what undoubtedly reduces the costs and increase the profit.

All presented digital marketing strategies bring numerous benefits in agriculture business as they enable the connection with the customers in an easier and faster manner, better understanding of their needs and preferences, sending customer-tailored messages, products, and services, improvement of the company-customer relationship, strengthening the company's brand, and boosting the sales and profit. However, the aim of any digital marketing strategy, alongside the development and delivery of personalized marketing messages, is to not be intrusive. Otherwise, they can lead to the opposite effects of the desired ones. Therefore, the evaluation of the implemented marketing techniques should be regularly performed.

Conclusion

Agriculture is one of the most important sectors that help boost economic growth. With the applications of ICTs, agriculture has become smarter and sustainable than ever before. At the same time, ICTs play a key role in the marketing domain of agribusiness. Digital marketing strategies have completely changed the way farmers and companies communicate with current and potential customers. Knowing what the customers want and need, and enabling them the right information, products, and services at the right time, at the proper spot and at the affordable prices is crucial for the success of agriculture business. The development of efficient and profitable digital agriculture marketing practice is not an easy task. It is a complex process that requires the intensive work of different professional teams throughout the entire agri-food sector. Effective and profitable agriculture marketing plan realized with the help of symbiotic approach of modern ICTs and marketing strategies will increase the customers' engagement, satisfaction, and loyalty, lead to stronger and internationally recognized brand, and boost sales and profits.

Abstract

In the Republic of Croatia beekeeping is a traditional and esteemed agricultural activity. Due to different climatic zones (continental, mountainous and Mediterranean), Croatia has different conditions for the development of beekeeping, and this variety and richness of plant species allows the production of many types of honey. However, for most beekeepers in Croatia beekeeping is an additional activity. The honey production has increased significantly since the year 2010, with the highest recorded production in 2015 (11,477 tons). The number of beekeepers in the Republic of Croatia decreased by 42% in 2018 compared to 2015, while the number of beehives decreased by 34% in the same period. Only 4% of beekeepers have more than 150 beehives, while 42% have 1 to 30 beehives. Mobile beekeeping makes it possible to achieve higher honey yields per beehive, but additional equipment is also needed which increases production costs, estimated at EUR 1,474.53 a year (registration, maintenance of vehicles, fuel and work required when moving beehives). In case 1 (stationary production) 16 kg of honey was produced and income of 35.97 euros per beehive was generated, while in case 2 (mobile beekeeping) 42 kg of honey was produced and income of 100.45 euros per beehive was generated.

Keywords: *Honey, income, mobile beekeeping, stationary beekeeping*.

Introduction

The beekeeping has a long tradition in the Republic of Croatia and the first written document about beekeeping is a Vinodol Code from the year 1288. The beekeeping is an important agricultural branch which through pollination, honey production and other bee-products impact the total economic activity, rural development and sustainable ecological balance (Šakić Bobić *et al.*, 2018). The Republic of Croatia has three different climatic zones (continental, mountainous and Mediterranean) and different conditions for beekeeping development which enables production of many different honey types (Kezić *et al.*, 2014). Beekeeping production has a great economic significance which is reflected in the production of honey, pollen, propolis, royal jelly, wax and bee venom (Vojvodić and Bubalo, 2017). According to the European Commission data (2017) the EU is a second world largest honey producer (250,000 ton annually), behind China with about 17 million beehives. The EU is a great honey importer and the first supplier is China with a 40% share at European honey market. The honey production in Croatia increased since the year 2010, with the biggest recorded production for the year 2015 (11,477 ton). In the year 2017 there were 8,805 ton of honey produced, which is four times more than in 2010 (FAOSTAT, 2019). According to the data from beekeepers and apiary records for the National Beekeeping Program for 2020-2022, in the year 2018 the number of beekeepers decreased by 42%, while the number of beehives decreased by 34%. A significant number of beekeepers (41%) are small (up to 30 beehives), 55% have between 31 and 150 beehives, while only 4% have more than 150 beehives. Professional beekeepers have a total of 64,663 beehives and their share is 17.38% of the total number of beekeepers. In average they have 242 beehives. 90% of beekeepers that produce honey on conventional way are mobile beekeepers, as well as 95% of those who are organic beekeepers. Beekeepers with a smaller number of beehives usually use one of the forms of direct sales (at farm gate, at local markets) for their honey. Increasing the number of beehives increases the share of wholesale. About 3/4 beekeepers use direct sale channels, while 1/4 sells through the wholesale. Selling in retail chains and supermarkets covers large suppliers and honey packing companies (Ministry of Agriculture, 2019). In the beekeeping there are two beekeeping methods, stationary and mobile. Mobile beekeeping requires higher costs, but it is possible to achieve 20-40 kg of honey per beehive more than by stationary beekeeping (Abrol, 2010). Efficient beekeeping today requires 50 to 60 kg of honey per beehive, and mobile beekeeping is the only way to achieve high yields. Mobile beekeeping requires additional equipment (vehicle), and beekeepers need certain locations to move their beehives (Ćejvanović *et al.*, 2011). The research of Grgić *et al.* (2009) shows that moving beehives may take advantage of the opportunities and thus produce an average of 60 kg of honey per beehive. The aim of this paper is to see the economic success of beekeeping in a mobile and stationary mode.

Material and Methods

Primary data were obtained by interviewing the beekeepers/owners, mobile and stationary (case study). The interview was conducted in the year 2018, for the data of previous production year. The stationary beekeeping farm is in the City of Zagreb and has 60 beehives (type LR and Farar). It is engaged in beekeeping since 2012 and has 6 family farm members. The mobile beekeeping farm is in the Brodsko-Posavska County (municipality of Garčin) and has 70 beehives (type LR) that moves around the surrounding area, depending on the pasture conditions. The farm owns a van and has 3 family farm members. Calculation of indicators was made on the obtained primary data, which are processed in Excel. The questionnaire included questions about the social conditions of family farm (number of household members, qualifications, ...), technological questions (type of beehives, method of beekeeping, production of honey and other products, ...), and economic questions (selling prices, production costs).

Results and Discussion

Case 1: Stationary beekeeping

The farm produces three types of honey (acacia, flower and chestnut) sold at an average price of 7.37 EUR/kg. The farm equipment value is estimated at 8,732.57 EUR. A total of 60 beehives produce 960 kg of honey, or 16 kg of honey per beehive.

Table 1. Equipment value and annual depreciation, EUR/year.

Equipment	Purchase value, EUR	Depreciation rate (%)	Annual depreciation, EUR
Beehives	5,630.03	10	563.00
Honeybee colonies	2,412.87	25	603.22
Electric embedder for wax foundation	22.79	10	2.28
Honey extractor	268.10	10	26.81
Smoker	12.06	10	1.21
Wax extractor	251.34	10	25.13
Inox barrel	56.30	10	5.63
Other equipment	79.09	25	20.00
TOTAL	8,732.57		1,247.05

*Source: Car (2019).

Honey is usually sold at farm gate, local markets and fairs, which confirms the data from bee products market current state analysis made for National Beekeeping Program, that small beekeepers sell through the direct sales channels. In addition to honey, the farm produces propolis tincture (about 30 ml per beehive) sold at a price of EUR 2.68 per 20 ml. The owner pays pension insurance and estimates that one beehive requires 6 hours of work per year. Although this work is carried out by family farm members, it was calculated for 3,62 EUR/h as the average monthly net wage per hour of work in agricultural production for the year 2017 (Croatian Bureau of Statistic).

Table 2. Calculation for stationary beekeeping production, EUR.

	Total (60 beehives), EUR	Per beehive, EUR
Honey	7,077.75	117.96
Propolis	241.29	4.02
I. TOTAL INCOME	7,319.03	121.98
Feeding	804.29	13.40
Package	211.13	3.52
Wax foundation	965.15	16.09
Labor	1,302.95	21.72
Veterinary cost	268.10	4.47
Beehives maintenance	160.86	2.68
Depreciation	1,247.05	20.78
Pensioner's insurance	201.07	3.35
II. TOTAL COST	5,160.59	86.01
III. FINANCIAL RESULT (I-II)	2,158.45	35.97
Economy (I/II)	1.4	
Productivity (I/hours of work)	20.33	
Profitability (III/equipment purchase value)	25%	

*Source: Car (2019).

Calculated financial indicators show that the farm producing bee products in a stationary manner with 60 beehives operates positively and achieves a satisfactory level of business profitability, although the quantity of honey produced per beehive is relatively small (16 kg). Similar research by Grgić et al. (2009) indicates that the average honey production per beehive in stationary beekeeping is 18.4 kg, with variations from 11.1 to 26.8 kg, which confirms that selected beekeeping farm as a case study may represent a type of stationary beekeeping in Croatia.

Case 2: Mobile beekeeping

The farm produces four types of honey (rapeseed, acacia, chestnut and sunflower) and sells it at an average selling price of 5.36 EUR/kg on the doorstep, local markets and fairs. It achieves a lower selling price when compared to the farm from Zagreb, which confirms the data of the Croatian Beekeeping Association collected by the Ministry of Agriculture survey that the retail prices of honey produced in Slavonia are significantly lower than those achieved in Zagreb and surrounding. The farm owns a honey extractor kit, a wax extractor, a pollen trap, electric embedder for wax foundation, a smoker, a protective clothing and a van for honeybee's colonies transportation, and the assets purchase value is estimated at EUR 16,159.52, of which 42% for the vehicle's value. It is evident that mobile beekeeping requires higher investment than stationary production, but it also records higher honey production per beehive (42 kg).

Table 3. Equipment value and annual depreciation, EUR/year.

Equipment	Purchase value, EUR	Depreciation rate (%)	Annual depreciation, EUR
Beehives	4,222.52	10	422.25
Honeybee colonies	2,815.01	25	703.75
Honey extractor	1,340.48	10	134.05
Wax extractor	375.34	10	37.53
Pollen trap	609.92	10	60.99
Electric embedder for wax foundation	26.81	10	2.68
Smoker	13.40	10	1.34
Protective clothing	53.62	25	13.40
Vehicle	6,702.41	20	1,340.48
TOTAL	16,159.52		2,716.49

*Source: Car (2019).

In addition to honey, the farm produces pollen, about one kilogram per beehive, and sells it for 10.72 EUR/kg. Farm is operated by farm members (420 hours of work a year) and seasonal workforce (140 hours a year). Vehicle registration, maintenance, fuel and lubricant costs are estimated at 1,474.53 EUR/year.

Table 4. Calculation for stationary beekeeping production, EUR.

	Total (70 beehives), EUR	Per beehive, EUR
Honey	15,764.08	225.20
Pollen	750.67	10.72
I. TOTAL INCOME	16,514.75	235.92
Feeding	797.59	11.39
Package	591.15	8.44
Wax foundation	938.34	13.40
Labor – farm members	1,520.11	21.72
Labor – seasonal workforce	506.70	7.24
Veterinary cost	938.34	13.40
Vehicle cost	1,474.53	21.06
Depreciation	2,716.49	38.81
II. TOTAL COST	9,483.24	135.47
III. FINANCIAL RESULT (I-II)	7,031.50	100.45
Economy (I/II)	1.7	
Productivity (I/hours of work)	29.49	
Profitability (III/equipment purchase value)	44%	

*Source: Car (2019).

Based on the calculated financial indicators, the farm with mobile beekeeping, despite the higher investment cost of equipment, achieves a positive financial result. Although it has a lower selling price of honey, it is compensated with higher yields per beehive. The cost structure is dominated by the cost of human labor with a 21% share in total cost, which is correlated with the research of Grgić et al. (2009).

Beekeeping farms selected as case studies show main trends in assets investment, structure and amount of working capital, as well as production and economic performance typical for two analyzed forms of beekeeping. Farmers with stationary beekeeping invest less per unit of production (beehive) and products (kg of honey), and based on basic economic indicators, can be satisfied with beekeeping as "a profitable hobby". Especially since part of the working hours of family members can be devoted to other bee products except honey. In mobile beekeeping there are many unknown variables influencing the high yield of honey (duration, dates and location at which bees are transported) during the beekeeping year, which do not allow significantly better economic results.

Conclusions

The paper presents two successful examples of beekeeping production, one with stationary beekeeping and 60 beehives, other with mobile beekeeping and 70 beehives.

Stationary beekeeper produces 16 kg of honey per beehive and generates additional income through the production of propolis. Although it achieves relatively small honey yields per beehive, the farm operates positively and achieves a financial result of 35.97 EUR/beehive with efficiency 1.4, productivity 20.33 EUR/hour and profitability 25%.

The farm with mobile beekeeping produces 42 kg of honey per beehive, and as an additional product offers floral powder. This farm has additional costs for vehicles needed for beehives transportation, but also requires more human labour. Despite the higher costs, the farm operates successfully and achieves a financial result of 100.45 EUR/beehive with efficiency 1.7, productivity 29.49 EUR/hour and profitability 44%. Although the increased investment in mobile beekeeping is economically justified, some producers are not deciding to go on it because the stationary beekeeping with less risk achieves satisfactory financial results.

Abstract

This study aims to identify the knowledge of extension agents at extension centers of the forms, causes and effects of climate change, and to identify the role of agricultural extension in addressing climate change. This study was conducted in all extension centers in Al-Gharbia governorate, Egypt, during December 2018. Data were collected from 68 respondents of agricultural extension agents affiliated to 17 extension centers; 51 respondents were males and 17 respondents were females, questioned through a personal interview questionnaire made especially for this purpose. Several statistical methods were used such as percentage and frequency tables. The most striking results of the study showed that 9.41% of the respondents had a high level of knowledge about the forms of climate change.76.47 % had a high level of knowledge about the causes of climate change, while 73.52 % had a high level of knowledge about the effects of such climate change. The most of respondent were aware of the role of agricultural extension in diminishing the causes of climate change and overcoming the effects of climate change. The effects of climate change on agricultural extension work were as follows: difficulties in implementing the action plan due to change in rain patterns, difficulties in running farms and applying new farming techniques, growing workload put on agricultural extension agents, and an increase in costs of training.

Keywords: *Agricultural extension, climate change, extension centers, Al-Gharbia governorate, Egypt.*

Introduction

The whole world today is interested in the global climate change due to their impacts on human existence. Climate change has serious future effects. El-Marsafawy (2007) defines it as "the total change in the earth's surface as a result of the gas emissions which, in turn, lead to global warming and the rise in the earth's surface temperature."

Climate change takes many forms; the most prominent are the increase in temperature, shortage of rainfall, windstorms and hurricanes, long periods of dryness and the failure to forecast the weather (Shankar, 2013). The reasons for these climate change can be natural or human. The latter can be divided into industrial reasons and agricultural ones. The total gas emissions from agriculture account for 15.7% of the total global warming gases resulting into climate change (Abu Hadeed, 2010).

As such, agriculture has a big share in causing climate change. It is affected by these changes as well. This appears in the decrease in crop yield and animal production; the increase in water consumption for irrigation, the increase in water levels on land, soil salt, the diminishing net farm revenue, the increase in diseases and plant insects, and the increase in the cotton yield (Abu Hadeed, 2010; EL-Marsfawy, 2009; Ifeanyi-obi et al., 2012; Nnadi et al., 2013; Al-Shaib et al. 2016; Abd Ella et al., 2018).

Agricultural extension has a vital role in facing climate change prior to their occurrence through informing farmers to amend their practices which lead to the increase in the greenhouse gases. It has also an essential role after the occurrence of climate change through

informing farmers of the practices which could diminish the impact of these changes, telling them of how to adapt with the changes and lessen their side effects on the agricultural sector (Saleh, 2009; Mustapha et al., 2012; Al-Shenawy et al., 2013; AL-Shaib et al., 2016; Abd Ella et al. 2018). In light of this, it seems necessary to identify the extent to which extension agents are aware of this climate change, and the role played by agriculture extension in facing and overcoming this phenomenon.
This study aims to identify the knowledge of extension agents at extension centers of the forms, causes and effects of climate change, their desire to participate in activities to overcome climate changes and to identify the role of agricultural extension in diminishing the causes of climate change and overcoming its effects. It also aims to identify the effects of climate change on agricultural extension work.

Material and Methods

This study has been conducted in all extension centers in Al-Gharbia governorate, Egypt, during December 2018. Data has been collected from 68 respondents of agricultural extension agents affiliated to 17 extension centers; 51 respondents are male and 17 respondents are female, through a personal interview questionnaire made especially for this purpose.
Research variables have been measured as follows:
Knowledge of the features of climate change has been measured through a tool containing 13 items. Participants have been asked about their knowledge of the features of climate change.
Knowledge of the reasons for climate change has been measured through a tool containing 14 items. Participants have been asked about their knowledge of the reasons for climate change.
Knowledge of the impact of climate change has been measured through a tool containing 14 items. Participants have been asked about their knowledge of the impact of climate change.
They have to choose one of three options (Yes, I do not know, and No), on a scale of three (1, 2 and 3 respectively). The real range has been divided into three groups: low knowledge, average knowledge and high knowledge.
Participants' desire to participate in the extension activities to face climate change, as well as their awareness of the role played by agricultural extension in facing them, has been studied, too.
Several statistical methods such as percentage and, frequency tables were used to analyze the data.

Results and Discussion

Knowledge of the features of climate changes:
Table 1 shows that 79.41% of the participants have a high level of knowledge of the features of climate change.

Table 1. Distribution of the participants' answers for the knowledge of the features of climate change

Knowledge of the features of climate change	Number	Percentage
Low level of knowledge	6	8.82
Average level of knowledge	8	11.77
High level of knowledge	54	79.41
Total	68	100

Source: Data collected and calculated from questionnaires.

Knowledge of the reasons for climate change

Table 2 shows that 76.47% of the respondents have a high level of knowledge of the reasons for climate change.

Table 2. Distribution of the respondents' answers for the knowledge of the reasons for climate change

Knowledge of the reasons for climate change	Number	Percentage
Low level of knowledge	9	13.24
Average level of knowledge	7	10.29
High level of knowledge	52	76.47
Total	68	100

Source: Data collected and calculated from questionnaires.

Knowledge of the impacts of climate change

Table 3 shows that 73.52% of the respondents have a high level of knowledge of the impacts of climate change.

Table 3. Distribution of the respondents' answers for the knowledge of the impacts of climate change

Knowledge of the impacts of climate changes	Number	Percentage
Low level of knowledge	9	13.24
Average level of knowledge	9	13.24
High level of knowledge	50	73.52
Total	68	100

Source: Data collected and calculated from questionnaires

The results of tables 1, 2 and 3 indicate that the respondents have high level of knowledge of the features, reasons for, and impact of climate change. This, in turn, reflects the fruit of the training they have already received in the field of climate change.

The desire to participate in extension activities to face climate change

Table 4 shows that 98.53% of the respondents have desire to participate in extension activities to face climate change. This is an indicator of their motivation and keen interest in achieving the goals of extension work to overcome this climate change, and diminish their negative impact on the agrarian sector.

Table 4. Distribution of the respondents' answers for the desire to participate in extension activities to face climate change

Desire to participate in extension activities	Number	Percentage
Have desire	67	13.24%
Do not have desire	1	13.24%
Total	68	100%

Source: Data collected and calculated from questionnaires.

The role of agricultural extension in diminishing the agricultural causes of climate change

Table 5 contains the respondents' answers to the role played by agricultural extension in diminishing the agricultural causes of climate change. Top on the list of the roles played by extension agents is informing farmers of the need to stop burning rice straw, and recycling it; 61 participants (89.1%) highlighted this role. Then, 60 participants (88.23%) have mentioned the role of the need not to increase the land allocated for growing rice. Finally, 58 participants

(85.29%) have pinned down the importance of informing about the environmental problems and pollution sources.

Table 5. Distribution of respondents' answers to the role played by agricultural extension to diminish the causes of climate change

The agricultural extension role	Frequency							
	Always	%	Sometimes	%	Rarely	%	Never	%
Less use of chemical fertilizers	54	79.41	13	19.12	1	1.47	-	-
Amending agricultural waste usage system	51	75	13	19.13	4	5.88	-	-
Not increasing the land for rice	60	88.23	7	10.29	1	1.47	-	-
Informing of environmental problems and pollution sources	58	85.29	10	14.71	-	-	-	-
Informing of the need not to overuse pesticides	52	76.47	15	22.06	1	1.47	-	-
Informing of the need to stop burning rice straw, and to reuse it	61	89.70	5	7.35	2	2.94	-	-
Increasing the culture of afforestation	52	76.47	15	22.06	6	8.82	-	-

diffusing the integrated pest management methods	50	73.53	17	25	1	1.47	-	-

Source: Data collected and calculated from questionnaires.

Being aware of the role played by agricultural extension in overcoming the impacts of climate change on agriculture:
Table 6 shows the extension agents' answers to the role of agriculture extension in overcoming the impact of climate change in agriculture. Top on the list of the roles are using new or genetically modified species, lessening the land that consumes a lot of water, growing legumes and green manures. 60 participants (88.23%) reported equal ratios for such roles. Next, 86.76% of the participants referred to the need to diffusion short-term species that need the least amount of water, and using new and advanced irrigation and sewage systems.

Table 6. Distribution of respondents' answers to the role played by agricultural extension to overcome the impact of climate change on agriculture

The agricultural extension role	Frequency							
	Always	%	Sometimes	%	Rarely	%	Never	%
Coping and adapting with climate changes	51	75	14	20.59	2	2.94	1	1.47
Informing of lessening the dangers related to climate changes	53	77.94	12	17.65	3	4.41	-	-
Using new or genetically modified species	60	88.23	6	8.82	1	1.47	1	1.47
diffusing short-term	59	86.76	7	10.29	1	1.47	1	1.47

The agricultural extension role	Frequency							
	Always	%	Sometimes	%	Rarely	%	Never	%
species that need the least amount of water								
Lessening the crops that need a lot of water	60	88.23	4	5.88	4	5.88	-	-
Using new and advanced irrigation and sewage methods	59	86.76	6	8.82	3	4.41	-	-

The problems of climate change and their impact on the agricultural extension work
Table 7 indicates the respondents' answers to the problems of climate change and their impact on the agricultural extension work. These can be descending ordered as follows: the difficulty in implementing the work plan because of rainfall conditions (57.35%), the difficulty in implementing farm administration and the new farm technologies (55.88%), overload of the extension agents' work (52.94%), increase in training costs (51.47%), difficulty in training farmers in a timely manner (33.82%), difficulty in persuading farmers of increasing their investments in agriculture (30.88%), and lastly doubt in the extension advice (19.12%).

Table 7. Distribution of respondents' answers to the problems of climate change and their impact on the agricultural extension work

Problem	Agree		Partly agree		Disagree	
	Number	%	Number	%	Number	%
Difficulty in persuading farmers of investing their money in agriculture	21	30.88	27	39.71	20	29.41
Difficulty in implementing the work plan because of rainfall conditions	39	57.35	25	36.76	4	5.88
Difficulty in training farmers in a timely manner	23	33.82	23	23.82	22	32.35
Difficulty in implementing farm administration and new farm technologies	38	55.88	14	20.59	16	32.53
Doubt in extension advice	13	19.12	33	48.53	22	32.35
Overload of the extension agents' work	36	52.94	15	22.06	17	25
Increase in the training costs	35	51.47	14	20.59	19	27.94

Source: Data collected and calculated from questionnaires.

Conclusions

In light of the foregoing discussion, it is clear that agricultural sector affects the climate change phenomenon, and vice versa. It is also clear that extension agents in the extension centers have high level knowledge of the features, reasons and impact of the climate change on agriculture. This is clearly reflected on their desire to participate in agricultural extension activities to face this phenomenon. They are full aware of the role played by agricultural extension in this mission, and to what extent the sector can achieve this goal. Agricultural extension spares no effort in facing climate change, whether through diminishing their causes, or adapting with their impact through informing farmers and their families of the proper agricultural practices.

Abstract

This study aims to identify the extension knowledge needs of rural women of the meaning, causes and effects of climate change phenomenon on agriculture, food and nutrition, public health, poultry raising, breeding and care of farm animals, and the field of protection and conservation of environmental resources. This study was conducted in some villages of Al-Gharbia Governorate, Egypt, from December 2018 to February 2019. Data were collected from 300 respondents, randomly selected multistage-clustered sample, through a personal interview questionnaire made especially for this purpose. Several statistical methods were used such as percentage and frequency tables. The most striking results of the study showed that 51.34% of respondents had a high extension knowledge need about the meaning of climate change phenomenon. 60.34% of respondents had a high extension knowledge need about the causes of the climate change phenomenon. 54.67%, 62%, 73.67%, 53.67%, 35.33%, 54.67% of respondents had a high extension knowledge need about the effects of climate change in order on; agriculture, food and nutrition, health, farm animal breeding, poultry, and the protection and maintenance of environmental resources, respectively.

Keywords: *Agricultural extension needs, climate change phenomenon, rural women, Al-Gharbia governorate, Egypt.*

Introduction

Climate change, more commonly known as global warming, is highly regarded by each country due to their impacts on human existence. Climate change has serious future effects and the reasons for these climate changes can be natural or human. The latter can be divided into industrial reasons and agricultural ones. The total gas emissions from agriculture account for 15.7% of the total global warming gases resulting into climate change (Abu Hadeed, 2010). So agriculture has a big share in causing climate change. It is affected by these changes as well. This appears in the decrease in crop yield and animal production; the increase in water consumption for irrigation, the increase in water levels on land, soil salt, the diminishing net farm revenue, the increase in diseases and plant insects, and the increase in the cotton yield (Abd Elhafez, 2007; Ifeanyi-obi et al., 2012; EL-Marsfawy, Nnadi et al., 2013; Al-Shaib et al. 2016; Abd Ella et al., 2018).

Agricultural extension has a vital role in facing climate changes prior to their occurrence through informing rural women to amend their practices which lead to the increase in the greenhouse gases. It has also an essential role after the occurrence of climate changes through informing rural women of the practices which could diminish the impact of these changes, telling them of how to adapt with the changes and lessen their side effects through training programs for rural women (Saleh, 2009; Keshta, 2012; Mustapha et al., 2012; El-Shenawy et al., 2013; AL-Shaib et al., 2016; Abd Ella et al. 2018).

The first step to create a good agricultural extension programs to increase rural women' awareness of climate change must be in accordance with the really extension needs of them (Yaghy, 1986). So, this study aims to identify the extension knowledge needs of rural women of the meaning, causes and effects of climate change phenomenon on agriculture, food and nutrition, public health, poultry raising, breeding and care of farm animals, and the field of protection and conservation of environmental resources.

Material and Methods

A multi-stage cluster sample of Gharbia villages was drawn yielding four sample villages. A sample of 75 rural women was selected from each sample village using the snowball technique; to be the total sample was 300 rural women. Data were collected from December 2018 to February 2019, through a personal interview questionnaire made especially for this purpose. Several statistical methods were used such as percentage and frequency tables.

The knowledge extension needs of respondents on the phenomenon of climate change were measured through several variables that measure their knowledge of aspects of the phenomenon as follows: the meaning of the phenomenon of climate change, the causes of climate change, the effect of Climate Change on the Study Areas, the effect of climate change on agriculture, the effect of climate change on food and nutrition, the effect of climate change on public health, the effect of climate change on poultry raising, the effect of climate change on breeding and care of farm animals, and the effect of climate change on the field of protection and conservation of environmental resources.

The knowledge extension needs were assessed as the degrees which complete perfect knowledge of each study variable. The total degree of knowledge extension needs according to the actual range of each study variable was divided into three levels: high knowledge extension needs, medium knowledge extension needs and low knowledge extension needs. Only the knowledge extension needs for the meaning of the phenomenon of climate change divided to two levels high and low; Knowledge needs for the meaning of the phenomenon of climate change: Were measured the rural women Knowledge needs of the concept of the phenomenon of climate change by asking the respondents about a specific concept of the phenomenon of climate change, and given answers values (2) to the correct answers; and that mean their knowledge needs about the concept of climate change phenomenon is low, So they do not need training of this aspect, and (1) those who did not know the answer; that mean their Knowledge needs of the concept of phenomenon is high, so they need training of this aspect. As shown in table (1).

Knowledge needs of rural women on the causes of climate change: were measured through a tool containing 12 items. Participants had asked about their knowledge of the all respondents were asked about their knowledge of the causes of climate change and a response was chosen from three responses: Yes, I do not know, and no, those responses had codes 3, 2, 1; respectively for the correct items and codes 1, 2, 3; to the Wrong items The answers obtained by each researcher were subtracted from the expected knowledge needs which 36 degrees. The real range has been divided into three groups: A low was less than 22, medium was from 22 to 29, and a high knowledge need was more than 29, so they need training of this aspect. As shown in table (2).

Knowledge Needs of the effect of Climate Change on the Study Areas:

Knowledge needs on the effect of climate change on agriculture: were measured through a tool containing 9 items. Participants had asked about their knowledge of the all respondents were asked about their knowledge of the effect of climate change on agriculture and a response was chosen from three responses: Yes, I do not know, and no, those responses had codes 3, 2, 1; respectively for the correct items and codes 1, 2, 3; to the Wrong items The answers obtained by each researcher were subtracted from the expected knowledge needs which 27 degrees. The real range has been divided into three groups: A low was less than 15, medium was from 15 to 20, and a high knowledge need was more than 20, so they need training of this aspect. As shown in table (3).

Knowledge needs on the effect of climate change on food and nutrition: were measured through a tool containing 9 items. Participants had asked about their knowledge of the all respondents were asked about their knowledge of the effect of climate change on food and nutrition and a response was chosen from three responses: Yes, I do not know, and no, those responses had codes 3, 2, 1; respectively for the correct items and codes 1, 2, 3; to the Wrong items The answers obtained by each researcher were subtracted from the expected knowledge needs which 27 degrees. The real range has been divided into three groups: A low was less than 16, medium was from 16 to 22, and a high knowledge need was more than 22, so they need training of this aspect. As shown in table (4).

Knowledge needs on the effect of climate change on public health were measured through a tool containing 9 items. Participants had asked about their knowledge of the all respondents were asked about their knowledge of the effect of climate change on public health and a response was chosen from three responses: Yes, I do not know, and no, those responses had codes 3, 2, 1; respectively for the correct items and codes 1, 2, 3; to the Wrong items The answers obtained by each researcher were subtracted from the expected knowledge needs which 27 degrees. The real range has been divided into three groups: A low was less than 16, medium was from 16 to 22, and a high knowledge need was more than 22, so they need training of this aspect. As shown in table (5).

Knowledge needs on the effect of climate change on poultry raising were measured through a tool containing 10 items. Participants had asked about their knowledge of the all respondents were asked about their knowledge of the effect of climate change on poultry raising and a response was chosen from three responses: Yes, I do not know, and no, those responses had codes 3, 2, 1; respectively for the correct items and codes 1, 2, 3; to the Wrong items The answers obtained by each researcher were subtracted from the expected knowledge needs which 30 degrees. The real range has been divided into three groups: A low was less than 17, medium was from 17 to 23, and a high knowledge need was more than 23, so they need training of this aspect. As shown in table (6).

Knowledge needs on the effect of climate change on breeding and care of farm animals: were measured through a tool containing 10 items. Participants had asked about their knowledge of the all respondents were asked about their knowledge of the effect of climate change on breeding and care of farm animals and a response was chosen from three responses: Yes, I do not know, and no, those responses had codes 3, 2, 1; respectively for the correct items and codes 1, 2, 3; to the Wrong items The answers obtained by each researcher were subtracted from the expected knowledge needs which 36 degrees. The real range has been divided into three groups: A low was less than 17, medium was from 17 to 23, and a high knowledge need was more than 23, so they need training of this aspect. As shown in table (7).

Knowledge needs on the effect of climate change on the field of protection and conservation of environmental resources: were measured through a tool containing 5 items. Participants had asked about their knowledge of the all respondents were asked about their knowledge of the effect of climate change on the field of protection and conservation of environmental resources and a response was chosen from three responses: Yes, I do not know, and no, those responses had codes 3, 2, 1; respectively for the correct items and codes 1, 2, 3; to the Wrong items The answers obtained by each researcher were subtracted from the expected knowledge needs which 36 degrees. The real range has been divided into three groups: A low was less than 9, medium was from 9 to 12, and a high knowledge need was more than 12, so they need training of this aspect. As shown in table (8).

Several statistical methods such as percentage and, frequency tables were used to analyze the data.

Results and Discussion

The meaning of the phenomenon of climate change:

Table 1 show that 51.33% of the participants have a high level of the knowledge extension needs for the meaning of the phenomenon of climate change.

Table 1: the knowledge extension needs' levels for the meaning of the phenomenon of climate change

Level	N	%
High (1)	**154**	**51.33**
Low (2)	**146**	**48.67**
Total	**300**	**100**

<u>The effect of climate change on poultry raising:</u>
Table6 show that 53.67% of the participants have a high level of the knowledge needs for effect of climate change on poultry raising.

Table 6: the knowledge extension needs' levels for the effect of climate change on poultry raising

Level	**N**	**%**
High (more than 23)	161	53.67
Average (from 17 to 23)	83	27.66
Low (less than 17)	56	18.67
Total	300	100

Source: Data collected and calculated from questionnaires. Mean: 21.88, Standard deviation: 5.16

<u>The effect of climate change on breeding and care of farm animals:</u>
Table7 show that 35.33% of the participants have a high level of the knowledge needs for effect of climate change on breeding and care of farm animals.

Table 7: the knowledge extension needs' levels for the effect of climate change on breeding and care of farm animals

Level	**N**	**%**
High (more than 23)	106	35.33
Average (from 17 to 23)	122	40.67
Low (less than 17)	72	24
Total	300	100

Source: Data collected and calculated from questionnaires. Mean: 21.38, Standard deviation: 3.16

<u>The effect of climate change on the field of protection and conservation of environmental resources:</u>
Table8 show that 54.67% of the participants have a high level of the knowledge needs for effect of climate change on the field of protection and conservation of environmental resources.

Table 8: the knowledge extension needs' levels for the effect of climate change on the field of protection and conservation of environmental resources

Level	N	%
High (more than 12)	164	54.67
Average (from 9 to 12)	98	32.67
Low (less than 9)	38	12.66
Total	300	100

Source: Data collected and calculated from questionnaires. Mean: 11.38, Standard deviation: 3.16

The results of all the tables indicate that the respondents had a high level of knowledge extension needs of the meaning of climate change, climate change phenomenon' reasons, and its effects on agriculture, food and nutrition, public health, poultry raising, breeding & care of farm animals, and the field of protection and conservation of environmental resources. This, in turn, reflects how rural women need lots of agricultural extension interest to develop their knowledge about climate change phenomenon, and learn how to adapt with it and lessen the side effects of this phenomenon.

Conclusions

In light of the foregoing discussion, it is clear that rural women are in great need to develop their knowledge of climate change phenomenon. This will only happen through agricultural extension programs which increase rural women awareness about the effects of climate change phenomenon.

Abstract

The main objective of the study was to identify the attitude of agricultural extension workers towards the applications of e-agriculture extension in Gharbia governorate. The size of the sample was determined by using the Krejcie & Morgan table. The sample encompassed 196 randomly selected participants according to the percentage of each category of agricultural extension workers in the overall. A questionnaire was distributed to the respondents during monthly meetings. Data were collected, and 192 cases were retrieved by 97.96%. Frequencies, percentages and T test were used for statistical analysis.The most important results were: Percentage of agricultural extension specialists 50.5% of sample size. About 80.7% of the respondents did not receive training courses in the field of e-agricultural extension. Only 39.6% of the respondents had computers connected to the Internet. 54.2% of respondents had a mobile phone with internet access. Half of the respondents had a low attitude towards e-agricultural extension. The most important problems of electronic agricultural extension were: lack of training of agricultural extension workers on e-agricultural extension, lack of Internet services in the work place, and lack of financial allocations to provide e-agricultural extension services.

Keywords: *E-agricultural extension application, ICT, VERCON, RADCON, Egypt.*

Introduction

The world now witnesses many economic, social and technological changes that have created a new reality of communication through information communication technology (ICT) applications. Now, the world is living the age of knowledge or ICT revolution. Information has become the power that can be used to increase the level of knowledge and a tool to influence the behavior of individuals in society (El-Baaly, 2011).

Agricultural extension is essential for achieving agricultural and rural development by exploiting all available resources and providing information and knowledge in all activities of rural life and changing rural knowledge, skills and attitudes, using various and different methods and means of guidance(Qamar,2005).

Traditional agricultural extension suffers from shortcomings in its methods and means of transferring agricultural knowledge, do not respond to the needs of the target audience, and lack effective mechanisms for interaction (Saleh, 2001; El-Baaly and El-Gohary, 2012, 2013).

Therefore, it was necessary to take advantage of the rapid developments in the field of information and communication technology based on the application and employment of computers and the Internet in the service of the agricultural extension sector and development through the provision of channels of communication wide and diverse as well as activating the role of information and communication technology, which provides the most appropriate communication environment for rural and agricultural development. The initiatives that employ ICT in agricultural extension should be seen as complementary to and not substitute for traditional extension services (Abdel Wahed, 2007, 2015).

The Agricultural Extension Service has recently introduced and applied ICT to overcome the difficulties faced by the agricultural extension system and the traditional extension methods and to increase their effectiveness. They are very powerful tools for learning rural people and providing them with the knowledge and skills they need to improve their living conditions. Development services, particularly in agricultural extension education, where ICTs constitute a fundamental change in the educational process (Qeshta, 2012).

Electronic extension is one of the forms of e-learning, so electronic extension can be defined as a new ICT-based extension system represented in computer technology and the Internet and made available to all users everywhere, all time, flexibly and easily (Qeshta, 2012; Abdel Wahed, 2015).

E-agricultural extension applications are a development in the communication channels in response to the ICT revolution. The Egyptian agricultural extension system has recently applied E-agricultural extension applications to overcome the difficulties faced by traditional extension methods and increase their efficiency. E-agricultural extension applications include: Agricultural Expert Systems, Virtual Extension and Research Communication Network (VERCON) http://www.vercon.sci.eg, Rural and Agricultural Development Communication Network (RADCON) http://www.radcon.sci.eg, Mobile Phone: M. Learning - M. Farming, and Social Media: Facebook https://www.facebook.com/Farmersuv-501445726675105/?fref=ts (El-Baaly,2018).

Although, e-agricultural extension applications improved agricultural extension service as an intelligent service, but diffusion of e-agricultural extension had not continued as expected. Therefore, the present study is intended to investigate the attitudes of agricultural extension workers towards E-agricultural extension applications.

The main objective of the study was to identify the attitudes of agricultural extension workers towards electronic extension in Al-Gharbia Governorate, Egypt by achieving the following sub-objective: (i) to identify the level of the attitudes of respondents towards E-agricultural extension applications (ii) To identify the differences between the attitudes of the respondents towards electronic agricultural extension when categorizing them on the basis of qualitative variables namely: job title, training in e-agricultural extension applications, availability of computer connected to the internet, availability of laptop connected to the Internet (iii) to identify the most important problems of e-agricultural extension applications from the point of view of the respondents and their proposals to solve them.

Research hypothesis:

To achieve the second research objective, the following research hypothesis was formulated: There are differences in the average scores of the attitude towards e-agriculture among respondents when classified according to: job title, training in e-agricultural extension applications, availability of a computer connected to the Internet, and availability of a laptop connected to the Internet. To test this hypothesis was formulated in its null hypothesis.

Material and Methods

There are 402 agricultural extension workers in Al-Gharbia Governorate. The size of the sample was determined by using the Krejcie & Morgan table (1970), 196 respondents were randomly selected. Data were collected from the respondents by interview questionnaire during the monthly meetings which were organized within 2018, and 192 cases were retrieved by 97.96% of whole sample.

A study of variables measured as follows:

<u>Job title:</u> There was a question about the job title. The responses were: Agricultural Extension Specialist, Agricultural extension agent, Responses were given (2, 1) in order.

<u>Obtained training in e-agricultural extension applications:</u> respondents were asked whether they received training courses in the field of e- agricultural extension applications or not, and the responses are: Yes or No and were given degrees (2.1), in order.

The availability of a computer connected to the Internet: It was expressed by the question of the availability of a computer connected to the Internet and whether or not the responses were: Yes or No and were given degrees (2.1), in order.
The availability of a mobile phone connected to the Internet: It was expressed by asking the question of the availability of a mobile phone connected to the Internet and the responses are: Yes or No and were given degrees (2, 1), in order.
The attitude of the respondents towards electronic agricultural extension: it is the main variable in the study. It has been measured through a tool containing 17 items. Participants have been asked about their response to each item was disagree, Partly agree, and agree, were given degrees 1, 2, 3 for positive items, and 3, 2, 1 were given for negative items, and the collection of degrees to express the researcher's attitudes towards electronic agricultural extension.
Problems of e-agricultural Extension: Each respondent was asked to identify the problems of e-agriculture according to his/her opinion..
Proposals to solve the problems of e-agricultural extension: each respondent was requested to identify appropriate solutions to overcome the problems of electronic agricultural extension.
Several statistical methods such as percentage, frequency and T- test were used to analyse the data.

Results and Discussion

A description of the study variables is presented hereinafter:
Job title:
Table 1 shows that 50.5% of the respondents are agricultural extension specialists and 49.5% of them are agricultural extension agent.

Table 1. Number and percentage distribution of respondents according to job title

Job title	Number	Percentage
agricultural extension specialists	97	50.5
agricultural extension agent	95	49.5
Total	192	100

Source: Data collected and calculated from questionnaires.

Obtain training in e- agricultural extension applications:
Table 2 shows that 80.7% of the respondents did not receive training courses e-agricultural extension applications. This may made negatively affect about their knowledge about e-agricultural extension applications, and its ability to provide an e-agricultural extension service as a smart service.

Table 2. Number and percentage distribution of respondents according to obtain training in e-agricultural extension applications

Obtain training in e-agricultural extension applications	Number	Percentage
Obtained training	37	19.3
Did not obtain training	155	80.7
Total	192	100

Source: Data collected and calculated from questionnaires.

This result indicates that, there are need to prepare intensive training programs for agricultural extension workers in the field of e-agricultural extension applications to improve their knowledge and experience, develop their skills and improve their abilities to benefit from the applications of e-agriculture to intelligent agricultural extension service.

The availability of a computer connected to the Internet:

Table 3 shows that only 55.2% of the respondents had computers. This percentage is not large in light of the call to activate the electronic agricultural extension.

Table 3. Number and percentage distribution of respondents according to computer availability

Availability of a computer	Number	Percentage
available	106	55.2
not available	86	44.8
Total	192	100

Source: Data collected and calculated from questionnaires.

Table 4 shows that 39.6% of the respondents had an internet computer. This is a small percentage despite the spread of Internet service in Al- Gharbia Governorate, Egypt. This may adversely affect the attitude towards e-agricultural extension applications.

Table 4. Number and percentage distribution of respondents by availability of computer connected to internet

computer connected to the Internet	Number	Percentage	Percentage of total sample
Available	76	71.7	39.6
Not available	30	28.3	10.6
The total number of respondents who have a computer	106	100	55.2

Source: Data collected and calculated from questionnaires.

The availability of a mobile phone connected to the Internet:

Table 5 shows that 94.3% of the respondents have a mobile phone. This is indicative of the spread of such technology, and that there is ease in the acquisition of mobile; perhaps for the price, ease of carrying and necessary in the communication of life in general.

Table 5. Number and percentage distribution of respondents according to their Mobile Phone Availability

Availability of a mobile phone	Number	Percentage
Available	181	94.3
Not available	11	5.7
Total	192	100

Source: Data collected and calculated from questionnaires.

Table 6 shows that 54.2% of the respondents have a mobile phone connected to the Internet; In other words, just over half of the respondents have the opportunity to deal with e-agriculture extension applications on the mobile phone connected to the Internet to obtain the agricultural extension information they need in their agricultural extension tasks and provide smart agricultural extension service.

Table 6. Number and percentage distribution of respondents by availability of Internet in Mobile Phone

Mobile connected to the Internet	Number	Percentage	Percentage of total sample
Available	104	57.5	54.2
Not available	77	42.5	40.1
Total number of respondents who have a mobile	181	100	94.3

Source: Data collected and calculated from questionnaire.

<u>The attitude of respondents towards e-agricultural extension:</u>
Table 7 shows responses of the respondents on the scale of the attitude towards e-agricultural extension, which indicated the weakness of attitudes towards e-agricultural extension, may be that because of weak awareness and training in e-agricultural extension field.

Table 7. Distribution of the responses of the respondents on the scale of attitude towards electronic agricultural extension

Items	Disagree		Partly agree		Agree	
	N	%	N	%	N	%
E-agricultural extension applications are complex and difficult.	57	29.7	31	16.1	104	54.2
Information obtained of e-agricultural extension applications is inaccurate.	41	21.4	50	16.2	101	52.6
Information obtained of e-agricultural extension applications is special.	118	61.5	39	20.3	35	18.2
Information obtained of e-agricultural extension applications is biased.	34	17.7	43	22.4	115	59.9
E-agricultural Extension applications are not a good source of agricultural information.	60	31.3	29	15.1	103	53.6
Information obtained of e-agricultural extension applications is uncertain results.	44	22.9	44	22.9	104	54.2
Information obtained of e-agricultural Extension applications is conflicting.	44	22.9	37	19.3	111	57.8
Encouragement the use of e-agricultural extension applications.	112	58.4	30	15.6	50	26
Information obtained of e-agricultural extension applications is applicable.	113	58.9	41	21.4	38	19.8
Information obtained of e-agricultural extension is consistent with other sources of agricultural information.	111	57.8	50	26	31	16.1
Information obtained of e-agricultural extension is credible.	110	57.3	49	25.5	33	17.2
E-agricultural extension applications are a waste of effort.	55	28.6	33	17.2	104	54.2
E-agricultural Extension applications are an effective method of communication between specialists.	105	54.7	37	19.3	50	26

Items	Disagree		Partly agree		Agree	
	N	%	N	%	N	%
E- agricultural Extension applications have become the best source of agricultural information.	112	58.4	51	26.6	29	15.1
E-agricultural extension applications are a waste of time.	58	30.2	27	14.1	107	55.7
E-Agricultural extension applications enable new agricultural information to be captured.	105	54.7	38	19.8	49	25.5
E-Agricultural Extension Applications inexpensive.	104	54.2	28	14.6	60	31.3

Source: Data collected and calculated from questionnaires.

In order to complete the view, the score of the items of the scale was collected to reflect the degree of attitude of each respondent. The actual range of the respondents was calculated. It was found to be 25 degrees; the lowest score was 17 and the highest score was 42. The actual range was divided into three sections as shown in Table 8; half of the respondents had a low positive attitude towards e-agricultural extension, while 5.2% of the respondents had an average positive response, and 44.8% of the respondents had a high positive attitude towards e-agricultural extension.

Table 8. Distribution of responses by respondents according to degree of attitude towards e-agricultural extension applications

Level of attitude toward e-agricultural extension	Number	Percentage
Low positive attitude from 17 to 25	96	50
Average positive attitude from 26 to 34	10	5.2
Positive attitude is high from 35 to 42	86	44.8
Total	192	100

Source: Data collected and calculated from questionnaires

The results of T-tests between the mean scores of the respondents' attitudes towards e-agricultural extension when classified according to independent variables qualitative:
Table 9 presents that there are significant differences in the attitude towards electronic agricultural extension applications among the respondents when they are classified on the basis of each of the qualitative independent variables namely: job title, training on e-agricultural extension applications, availability of computer connected to the Internet, availability of mobile phone connected to the Internet, Calculated (T) are 6.93, 3.66, 17.17 and 13.99 respectively, which are significant values at a significant level of 0.01. This result supports the research hypothesis.

Table 9. The results of T-tests of the differences between the mean scores of the respondents' attitudes towards e-agricultural extension when classified according to the independent variable categories

Independent variables		Mean scores of the respondents' attitudes towards e-agricultural extension	T value
Job title	Agricultural Extension Specialist	33.70	6.93 **
	Agricultural extension agent	23.03	
Training in e-agricultural extension applications	had training	34.65	3.66 **
	had not training	26.93	
Availability a computer connected to the Internet	available	39.85	17.17**
	unavailable	20.93	
Availability a mobile phone connected to the Internet	available	37.61	13.99**
	unavailable	20.64	

** Statistical significance at the level of 0.01

Problems of e-agriculture extension applications and proposed Solutions:
Table 10 shows that respondents identified ten problems of e-agricultural extension problems. Lack of training in the e-agricultural extension applications was in the top of the problems by 83.2% of responses, followed by lack of Internet services in the workplace of agricultural extension workers by 79.2% of respondents' answers.

Table 10. Respondents' answers about problems of e-agricultural extension applications

Problems	Frequencies	Percentages
Lack of training in e-agricultural extension applications.	160	83.2
Lack of Internet services in the work place of agricultural extension workers.	152	79.2
Lack of funding for electronic agricultural extension.	148	77
Continuous disruption of the Internet in the workplace of agricultural extension.	144	75
Lack of maintenance of computers.	138	71.8
E-agricultural extension applications are not updated regularly.	132	68.8
Lack of computers in the workplaces of agricultural extension.	128	66.6
High costs of e-agricultural extension applications.	108	56.2
Lack of e-agricultural extension applications.	100	52.1
Believes that e-agricultural extension is not important.	92	47.9

Source: Data collected and calculated from questionnaires.

Most of these problems appear to be related to the continued lack of funding for e-agricultural extension services after the initial pilot phases, which it are often funded by foreign projects or grants, and there are indicators confirming that success of e-agricultural extension applications as smart agricultural extension services in Egypt .
Proposals to solve the problems of e-agricultural extension from the point of view of respondents:

Table 11 that the respondents' suggestions solutions to problems of e-agricultural extension. The proposed solutions are arranged in descending order according to the answers of the respondents as follows: training agricultural extension workers on e-agricultural extension applications, connecting the internet service to the work place of the agricultural extension, providing periodic maintenance of electronic devices, updating information on e-agricultural extension applications, providing agricultural extension' workplaces with a sufficient number of computers, and other solutions.

Table 11. Respondents' suggestions solutions to problems of e-agricultural extension

Suggestions solutions	Frequencies	Percentages
Training agricultural extension workers on e-agricultural extension applications.	160	83.2
Connecting the Internet service to the work place of agricultural extension.	152	79.2
Providing periodic maintenance of electronic devices.	138	71.8
Updating information on e-agricultural extension applications.	132	68.8
Providing agricultural extension' workplaces with a sufficient number of computers.	128	66.6
Linking agricultural extension work to Internet.	77	40.1
Provide an incentive to encourage the use of e-agricultural extension applications.	74	38.5
Providing agricultural extension system with information technology experts.	74	38
Recruitment of young cadres able to use ICT in agricultural extension.	71	37
Diffusion awareness of the culture of electronic agricultural extension.	47	38.6

Source: Data collected and calculated from questionnaires.

Conclusions

The extension service can be provided through e-agricultural extension applications and can be offered in partnership and coordination between traditional agricultural extension and e-agricultural extension applications, and can only be provided through conventional agricultural extension according to the requirements of each extension situation and the circumstances of each extension agent.

There are several mechanisms to ensure that continue funding, whether by providing services entirely free of government funding or through various agricultural companies that invest in selling their products and marketing their services or paying the cost through the farmers' organizations that can be formed and Contractual farming with Agri-value chains , or directly pay farmers according to the number of their transactions specially when they use the most specialized services of high value, or adoption a combination of the previous methods.

Recommendations

Based on findings of the study there are practical/theoretical/political implications and originality/value, so it is possible to recommend:

(1) Preparation and implementation of training programs in the field of e-agricultural extension applications.

(2) Provide adequate financial allocations to activate the e-agricultural extension and ensure its continuity.

(3) Link agricultural extension services to an electronic database through smart cards for farmers.
(4) Providing advanced computers connected to the Internet in agricultural extension workplaces.
(5) Updating available agricultural information on e-agricultural extension applications.

Abstract

Tunis Village, Fayoum governorate, Egypt, is considered a successful model in Egypt inmaking full use of handcraft in promoting the Village and achieving sustainable tourism development.This research aims at exploring the current status of Pottery handcraft in Tunis Village and assessing its role as a tool for tourism promotion and achieving sustainable development in the Village.Three segments were surveyed in July 2019; the first segment is Pottery crafters where forty Pottery crafters were interviewed, while the second segment are the Tourists where unstructured face to face interviews conducted with fifteen tourists, and finally a survey was directed to Tunis Village's Local residents (non-crafters) where thirty questionnaires were completed. The results revealed that allPottery crafters indicated that the profession helped them to provide better education and health care to their families, they stated also that they are feeling safe and social secure. Both craftersand tourists stated that the Potteryhandicraft is main motivationfor tourists to visit Tunis Village. The most important challenges facing the profession of handicrafts are high prices of raw materials, as well as the great effort and long time needed for the preparing and processing the raw materials till it become ready for shaping.Local residentsstated that Potteryworkshops have attracted the tourists to visit the village, the matter which enabled them to increase and diversify their source of income, as it has created many Tourism related jobs. The researchhas come up with a number of recommendations to sustain the model of Tunis Villagewhich managed to use the Handicrafts inachieving sustainable tourism development, among these recommendations;making some modifications in the furnaces to reduce the emissions generated during firing the products and holding special events such as exhibitions, fairs and festivals showcase Pottery handcraft products, especially in the low season in summer.

Keywords: *Sustainable development, Rural tourism, Tunis village,.Pottery handicrafts*

Introduction

Cultural industries now play a major role in tourism marketing and development. Many countries all over the world started to use handicrafts as the main core in tourism development and marketing, establish the tourism facilities near main handicrafts production centers. Some develop cultural itineraries that focus on showing tourists and visitors such valuable intangible heritage. Egypt is famous for its traditional handicrafts since the beginning of the history, many handcraft clusters are scattered everywhere along the country. Despite this fact, the Egyptian tourism in Egypt has been shortened to just one product which the leisure tourism which represents almost 96% out of the inbound tourism in Egypt the matter which means that Egypt didn't get benefited from the existence of such valuable cultural heritage.

Handicrafts definition and importance

There are different definitionsfor the term handicraft;maybe the most acceptable one is the one that has been adopted by UNESCO In 1977 at Manila during a syposthym Symposium on Crafts, at which Handicrafts are defined as:

"*a type of work produced by artisans, either completely by hand, or with the help of hand-tools or even mechanical means, as long as the direct manual contribution of the artisan remains the most substantial component of the finished product. These are produced without restriction in terms of quantity and using raw materials from sustainable resources. The special nature of artisan products derives from their distinctive features, which can be utilitarian, aesthetic, artistic, creative, culturally attached, decorative, functional, traditional, religiously and socially symbolic and significant."*
The handicrafts sector has attracted the global attention long time ago, due to its cultural and socio-economic importance; as from the cultural point of view Handicrafts are considered a valuable component of the intangible heritage of any society, it represents its culture, history and traditions (India-craft, 2013).
The craft sector alsohas a great Socio-Economic importance as it is considered a home-based industry that needs minimum spending and facilities, simple instruments and comparatively brief apprenticeship or training depending on the complexity of the craft. The matter which makes this sector one of the biggest and most important employers without the need for big investments.
The home –based nature of the craft sector has given the chance for both males and females to join itespecially in rural areas where the conservative social system put restrictions on women leaving their household even if there are searching for an income-earning activity.
The craft sector also -in most cases- is a clean, environmentally-friendly industry which uses the available raw materials in the environment.
These incredible features of handicraft sector have made it an excellent tool that can play a major role in promoting sustainable development, as one can notice that it covers the three main dimensions of sustainable development; the social, economic, environmental.
In this regard and for all what have been mentioned above that shows the significance of craft sector, many industrialized and developing countries have exerted great efforts to preserve, develop and promote this sector, the upcoming figures show to which extent these countries have managed to make full use of the craft sectore as a tool for achieving sustainable development.
In Italy, the craft sector employees around 1/5 of the total number of workers and exports from Italian crafts constitute 17% of its Gross Domestic Product In Thailand the total number of craftspeople is 2 million. In Morocco, The handicrafts exports are estimated at US$ 63 million. While In Tunisia the craft sector employs about 300,000 craftspeople (11% of the active population) and the sector accounts for 3.8% of the Gross Domestic Product. In Vietnam the craft sector is adding around US$ 109 million annually to the country's GDP, as the sector provides 1.5 job opportunities for locals most of them from rural Areas . (USAID, 2008; Ngo, Duc Anhm, 2005). In India the exports of handicrafts reached $3.2 billion in 2005-06. (Richard 2007)

Handicraft and Tourism

In general the craft and tourism sectors are connected to each other, as traditional handicraftsare considered among the authentic cultural products made by the indigenous people of the hosting destination that tourists eager to see and purchase, which means that the Handicrafts as one aspect of traditional indigenous culture can be used as a good tool for marketing the destination and attracting more tourists.
In this regard, many destinations all over the world have managed to make full use of Handicrafts as a cultural product in their national tourism promotional campaigns, to diversify their exhibited tourism products and increase the overall attractionsof the destination to be able toattract large number of tourists.The matter did not limit to using Handicraft in the promotional campaign, but also different destinations all over the world have developed a

number of tourism – related handicrafts itineraries that enable the tourists to see the process of making a certain craft or even to participate in the production of a certain product.
Tourism also is considered a very effective tool for handicraft marketing, according to WTO tourist spends around 20 – 80$ on average on Handicrafts product purchases, as they want a tangible item to take back home that would remind them about the destination they visited and the indigenous people they have seen and the memories they have made (Wicks, 2004).
According to the figures handicrafts are considered among the most important tourism sub-sectors; accommodation, food and drink, handicrafts and excursions, with regard to generating pro-poor income (ITC, 2010) as around 55%.

The case of Tunis Village

It is situated 95 km south west of Cairo; it is a Village inYoussef AL Sedik District in Fayoum governorate. Overlooking one of the natural protected Areas in Egypt known as Qaraoun Lake.
In the 1980s, Evelyne Porret, a Potter from Switzerland, decided to stay in TunisVillagewith her Husband, and then she started to establish a PotterySchool to teach children of the VillageHow to shape Pottery. She was the first potter in the Village;she managed to train many of the local children in the craft of Pottery. The first generation of her students after being trained in the Pottery School, they manage to establish their own Pottery workshops.
The establishment of Pottery School was the turning point of Tunis Villageas it was the main reason to turn the Village into a large tourist destination visited by many visitors interested in watching the Pottery products being made by the crafters.The matter which motivates some locals and investors to establish a number of Hotels and cafeterias and other tourism services to provide tourists and visitors with the services which they are looking for.Also some of the local have shifted from their traditional career as farmers into a tourism related professions like local tour guides, Safari drivers, Hotels employees …etc.

Research Question and Objectives

The current research is trying to answer the following question:
To what extent the Pottery craft has contributed in achieving sustainable tourism development in the village?
The main objectives of this research can be summed up in the following points:

1- To explore the current status of Pottery handcraft in Tunis Villageand define the main challenges which face this profession.
2- To assess to what extent the Pottery handcraft in Tunis Villagemanaged to improve the life of the local community by alleviating poverty, creating more job opportunities.
3- To assess to what extent the Pottery handcraft has become a tool for achieving sustainable tourism development.
4- To provide an action plan towards the preservation and development of Pottery handcraft in Tunis Village.

Material and Methods

The research was implemented by linking qualitative and quantitative data as well as qualitative observations.

Primary data

The information produced in this research is based on extensive fieldwork. Three surveys were conducted for the purpose of this research study. The first survey directed to the Pottery crafters in Tunis Village where a total of 40 questionnaires were distributed by the researchers. The qustionnairs is divided into thre parts; the first part is focusing on collecting general information about the crafter, the second part is focusing on collecting data about the

Socail and economic impact of the profession on the crafter himself/herself and on the Village in general, while the third part is focusing on the threats that may negatively affect the sustainability of Tunis Village. Unstructured face to face interviews were conducted with 15 tourists how were visiting Tunis Village during July 2019 to identify their level of satisfaction about Pottery craft and their recommendations to promote and develop such important craft. The selection of this segment was based on the willingness and availability of tourists to complete the questionnaire.
The third survey was directed to Tunis Village's Local residents (non- crafters) where a total of 30 questionnaires were completed. The main aim of this questioner is to explore their opinion about the Pottery craft and its impact on their social and economic life.

Secondary data

This research is based on comprehensive reading of many published references and other reliable internet sources which showed that Pottery handcraft is a very important unique selling point which resulted in attracting tourists, establishment of different hotels and cafeterias to provide tourists with accommodation, food and beverage.

Results and Discussion

Opinions of handcrafters, tourists, as well as local residents (non-crafters) were investigated to examine to what extent the Pottery craft has contributed in achieving sustainable tourism development in the village, the resultsare as follows:

PotteryHandcrafters

Among the crafters, results showed that 92.5% are males and only 7.5% are females; this is due to the conservative lifestyle in the rural areas long time ago which doesn't allow girls and women to learn this profession unlike these days where many families accept to teach their daughters the profession. The education level of crafters in Tunis Villageis a moderate in general: 20% of craftershad no formal education and they are illiterate, 32.5% of the farmers interviewed had obtained high school education, while only 2.5% had obtained bachelor degree, and 45% of them are young teenagers who still studying. Results revealed that 52.5% of Pottery crafters learnt the profession in "School of Pottery" that belongs to "Evelyne Porret" who early started the profession in Tunis since 1980, while 47.5% learnt it in the private workshops that have been established by the first generation of the Crafters who were trained by Evelyne . 100% of Pottery crafters indicated that the profession helped them to provide better education and health care to their families, they stated also that they are feeling safe and social secure by work in this profession. An 87.5% of crafters indicated that the profession achieves stability in their incomes, while 12.5% of them stated that it provide them with a partial stability in their incomes because sales volume is based more on seasonality as the sales usually go down during the summer season. As an average, Pottery crafters indicated that their income have been increased by 46.5% after working in the profession. A 100% of Pottery crafters are satisfied with work environment of the profession, while 87.5% of them agreed that the profession contributed to the reduction of unemployment in the village.
Pottery crafters stated that they take approximately 5 years as an average to learn the profession.

Table (1) Time to learn profession and percentage of income increase after profession

	N	Minimum	Maximum	Mean	Std. Deviation
Time to learn Pottery crafts' profession	40	0.5	15	4.91	2.78
Income increase % as working in profession	40	0	100	46.50	34.27

Source: field data, 2019

An 80% of crafters indicated that they receive support from government or private sector such as the training activities which provided by an Egyptian Italian project one of the UNDP development projects, moreover, the initiative of "Bank of Alexandria", where the bank provided electric wheels instead of manual one, the bank also sponsors the famous Handicraft festival of Tunis which take place in November each year.
A 100% of Pottery crafters confirmed that the Pottery industry in the Villageis what made Tunis its current form. "Ceramic products attracted tourism to Tunis, not vice versa". But then tourism has greatly contributed to the revival of the profession by providing buyers and increasing the demand for those products through domestic and foreign tourism.

Table (2) socioeconomic Characteristics of Pottery crafters

Sample description		Frequency	%
Gender	Male	37	92.5
	Female	3	7.5
	Total	40	100
Education level	Still studying	18	45
	Illiterate	8	20
	High school	13	32.5
	Bachelor or more	1	2.5
	Total	40	100

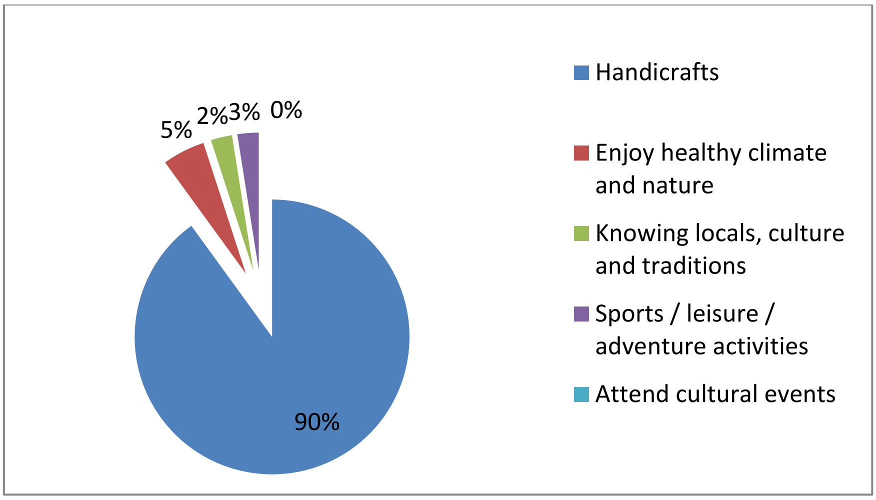
	Partly stable	5	12.5
	Total	40	100
Receiving support from government or private sector	Yes	32	80
	No	8	20
	Total	40	100
Contribution of profession to the reduction of unemployment in Tunis village	Yes (to a large extent)	35	87.5
	To some extent (partly)	5	12.5
	total	40	100

Source: field data, 2019

Crafters were asked to list the primary categories of buyers for their products; they stated that around 60% as an average are local buyers, while 40% are tourists and wholesalers. Given their marketing outlets, they market around 72% of their products directly to the end user, while the rest are sold tointimidators.
Crafters indicated that the most important challenges facing the profession of handicrafts are the continuous rise in the prices of raw materials and the difficulties of obtaining it, as well as the great time wasted in preparing and processing the raw materials, which consumes the time

of the artist and reduces his/ her production in quantity and quality. Among the most important challenges is the absence of information about foreign markets and its requirements as well as the exploitation of traders, moreover, the inability to produce a big quantity because of using traditional production methods such as ovens and hand-held wheels.



Graph (1) The main reasons for tourists to visit and stay in Tunis Village
Source: field data, 2019

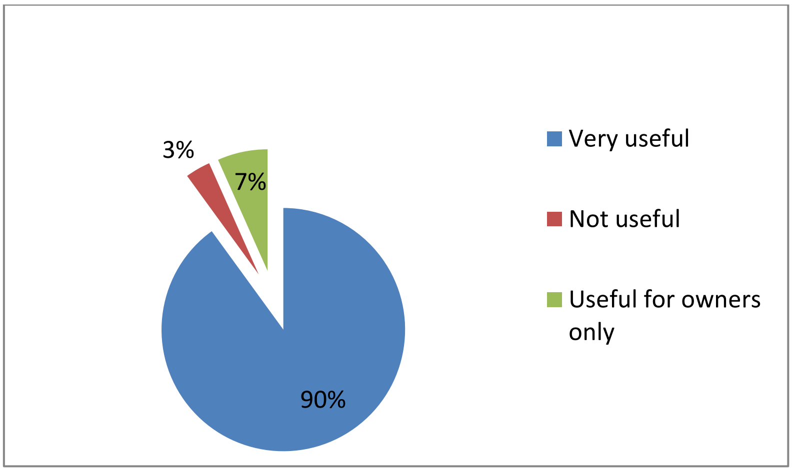
As it is shown in Graph(1), most of the crafters have agreed there are number of reasons that motivate the tourists to visit Tunis Village, but from their point of view the main motivation of the tourists to visit Tunis Village is to see Pottery School and workshops as well as to buy some Pottery products as souvenirs that would commemorate their visit to the village, they said that before the establishment of the Pottery school and other Pottery workshops Tunis Village was like any agricultural traditional EgyptianVillages and there was no tourism activity in the village, but after the establishment of the Pottery school and workshops the tourists started to feel motivated to visit the village, hotels and other tourism facilities and activities started to exist to fulfill the needs of the tourists.

Tourists/visitors (customers)

Unstructured face to face interviews were conducted with 15 tourists while they were visiting Tunis Village during July 2019, all of them have agreed that they have read about Tunis before visiting it, especially the story of the establishment of the Pottery school by the Swiss artist and engaging the locals and shifting the ordinary Egyptian Village into Eco-friendly touristic destination, and this is considered their main motivation for visiting Tunis village. They have shown a great level of satisfaction with the Pottery workshops and the final products. But the same time they have highlighted some issues that need to be dealt with in order to improve the business and sustain this great model, among these issues is the big gap in prices of the Pottery products in each workshop. Also they stated that it is important to train the crafters on how to diversify their final products to increase their customers as according to the respondents the Pottery products which are produced by the 13 workshops and the Pottery School are very similar to each other. Also they highlighted that establishment of an entity like NGO for example to help the crafter to overcome them challenges they face would positively affect the business and the Village as a whole.

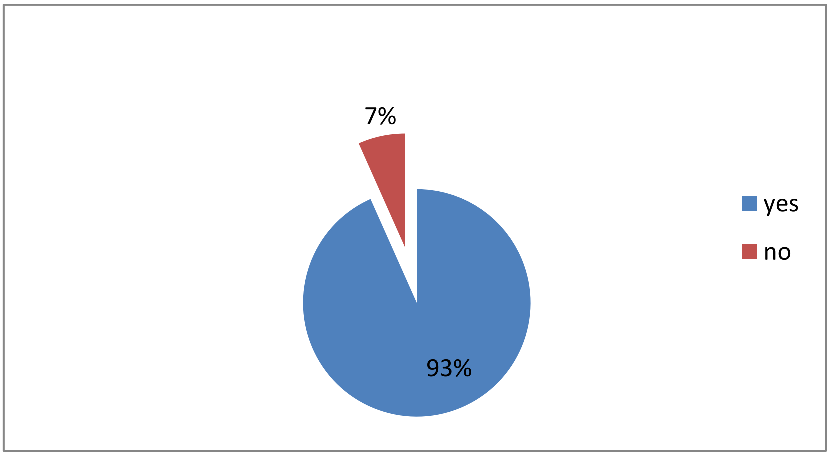
Local residents (non-crafters)

A 90% of local residentsinterviewed have a positive impression about Pottery workshops, while 7% of them think that these workshops are useful just for owners and who directly work in it, and a 3% of them think that it is not useful for the Village at all.



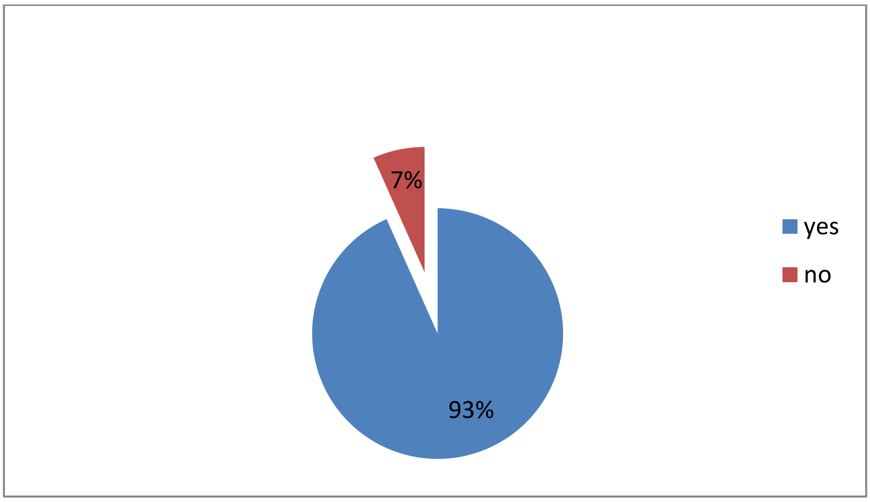
Graph (2) Impression of locals (non-crafters) about the pottery workshops
Source: field data, 2019

93% of locals (non-crafters) indicated that Pottery workshops benefit the Village in general. They think that it brought development to the whole Village through providing jobs opportunities in these workshops, hotels, and other tourism activities. It brought infrastructure which benefits all population at the village.



Graph (3) pottery workshops benefits in general to the Village
Source: field data, 2019

As it is shown in graph (4) 93% of the non-craftersrespondentshave mentioned that the existence of the Pottery School and workshops has attracted the tourists to visit the village,the matter which capacitates the non-craftersto increase and diversify their source of income, as it has created many Tourism – related jobs like tour operators, drivers, local tour guides, hotels owners and staff, coffee shops owner and staff…etc. Also they have mentioned that in each family in the Village at least there is a person who works in field Potteryhandicraft; all of these job opportunities have motivated their family members, who used to leave the Village to search for a job opportunity in Cairo, to stay at the Village and start their own business.



Graph (4)benefits of locals (non-crafters) in the Villagefrom pottery workshops
Source: field data, 2019

As a result of the increase of the tourism demand on the Village and their growing interest to taste the local healthy food, this fact has provide the females of the Village with a precious chance to fulfill the need of the tourists and earn a substantial amount of moneythrough the establishment of what so called a "community kitchen" in the Village where a group of the females meet to cock healthy local affordable and offer it to the tourist during their visit to the village.

Conclusion

The establishment of Pottery School was the turning point of Tunis Village as it was the main reason to turn the Village into a large tourist destination visited more than 120.000 tourists each year according to the village council, to watch the Pottery products being made by the crafters.The theoretical and the fieldwork have shown that Pottery handicraft has been playing a significant role in tourism promotion of the village; it also played a major role in achieving sustainable Development in the Village the matter which made Tunis Village Unique model which is totally different from any Craft Village in Egypt.
This piece of research proved that most of the local residents of the Village eitherPottery Crafters or non-Crafters are satisfied with the existence of Pottery workshops in the Village, they also feel satisfied with their income, this status has motivated the younger generations in the Villageto be motivated to learn the craft in order to start their own business.
A number of recommendations has been developed for ensuring the sustainability of this successful model, these recommendations include:

- Capacity building and technical Training workshops should be conducted to enhance the soft and technical skills of the Pottery crafters to assure better quality, pricing, packaging of final products.
- Holding special events such as exhibitions, fairs and festivals showcase Pottery handcraft products, especially in the low season (summer season) to motivate international and local tourists to visit the Village and push up sales during this season.
- Making some modifications in the furnaces to reduce the emissions generated during firing the products.
- An entilty (like NGO) should be established to to help the crafter to overcome them challenges they face especialy the procurement of the raw materials.

- The final products have to be diversified to expand the current market by addressing the demand a wide range of customers while taking into consideration the cultural idientity of the village
- Marketing the experience as well as the tangible products, throughorganizing tourism itineraries for tourists who are interested in how things are made or those who would like to take part in the production process as this will enhance the overall experience of the visitors and also will push up the sales of the tangible products.

THE ROLE OF INNOVATION SUPPORT SERVICE PROVIDERS IN AGRICULTURAL INNOVATION MANAGEMENT

Hannu E. S. HAAPALA*

Agrinnotech, Seinäjoki, Finland
*Corresponding author: hannu.haapala@agrinnotech.com

Abstract

Innovations in agriculture tend to be slow because of the conservativeness of the agricultural sector. 'Sustainable Precision Farming through User-Centered Design', a research project of the author funded by the Co-operative Research Programme (CRP) of the Organisation for Economic Co-operation and Development (OECD), suggests that the adoption phase of innovation is a major reason for the slowness. Adoption could be better if the R&D process was more user-centred. In order to succeed in this challenge, the participation of end-users in innovation should be much more efficient. All actors in innovation should gain more skills in User-Centred Design (UCD). The adoption phase needs more support from advisory services or consultancies. This is because the potential benefits of innovations are not realized if the adoption is inefficient. A Horizon 2020-funded research project, 'AgriSpin – Space for Innovations in Agriculture', aimed to find efficient methods to enhance innovation. In AgriSpin, there were 15 partner organizations from 12 countries. The goal of AgriSpin was to systematically explore Innovation Support Service Providers (ISSPs) in agriculture and rural development across Europe. The overall goal was to help create a stimulating environment for innovations. The results point out the urgent need for effective Multi-Actor Approach (MAA) to support all phases of innovation. The paper promotes the role of ISSPs as actors in efficient agricultural innovation. The growing need of agricultural engineering consultancy is discussed. Needs for further research and development are outlined.

Keywords: *innovation management, agriculture, User-Centred Design, Multi-Actor Approach.*

Introduction

Joseph Schumpeter, who is regarded as one of the most important economists in the first half of twentieth century, defined innovations in early 1900's. Real innovations should produce significant benefits for their users. Furthermore, he claimed, innovation driven by entrepreneurs is the most important reason for economic growth (Schumpeter 1912; Opie 1983; McCraw 2010; Drejer 2004; Śledzik 2013).

Scumpeter divided the innovation process into four dimensions: invention, innovation, diffusion and imitation. He puts the dynamic entrepreneur in the middle of his analysis. The entrepreneur, drawing upon the discoveries of scientists and inventors, creates completely new opportunities for investment, growth and employment. The invention phase or the basic innovation has less impact, while the diffusion and imitation process have a much greater influence on the state of an economy (Śledzik 2013).

In other words, innovations never reach the real innovation level, where the benefits are realized, without efficient adoption (diffusion and imitation). When widely adopted, the better artifacts, methods or systems produce their best benefits for their users and the surrounding society as well. Only then they can be called real innovations.

In agricultural innovations, the role of users (entrepreneurs in Schumpeterian thinking) has traditionally been important. Farmers have developed and introduced the new or gradually advanced machines and production methods. However, as recently noticed by several researchers, the social process of trust building in novelties takes considerably long time

(Kaasinen 2005). Wider adoption of the new solutions happens only after a period of successful application (Li et al. 2008). In agriculture, this is evident for systems level innovations such as Precision Farming (PF) (Diekman & Batte 2010; Haapala 2013).
New technologies are often hard to learn, remember and use so that usability issues make the adoption slow (Nielsen 1996). Again, PF is a good example of this (Haapala & Nurkka 2006).
Who else than the farmers themselves supports the innovation process in agriculture? In history, the process of innovation adoption in agriculture has been supported mainly by local actors such as the innovators themselves and other farmers who have acted as early-adopters. In many countries the church has been active in delivering knowledge of e.g. new technological developments and plant varieties. Manufacturers and sellers of agricultural machinery have then taken the role of innovation supporters. Later on, special ISSPs (Innovation Support Service Providers) have entered the market. Advisory services have been established and universities have opened extension services to apply their scientific findings in practice (Russel 1966; Lehto 2010; Knierim et al. 2015; Jones & Garforth 2019).
Nowadays there is a multitude of ISSPs to choose from. Their owners are either private or governmental, and they act, respectively, according to profit or non-profit principle. Systems level thinking is growing so that the interaction of agricultural innovators with other branches of innovation and the surrounding society is growing. As the innovations are getting complicated, new specialized consultancies have emerged. Innovation Brokers are entering the market and special funding programmes are built to support rural innovation (Klerkx & Leeuwis 2009; Batterink et al. 2010; Knierim et al. 2015; Jones & Garforth 2019).
The objective of the paper is to focus on the adoption phase of innovation in agriculture. The possible remedies for the slow speed towards real innovation are discussed. Particularly the role of ISSPs is investigated. Conclusions are made on the needed actions.

Material and Methods

The paper is based on two research projects. The first one, 'Sustainable Precision Farming through User-Centred Design' (2011-2012), was funded by the CRP (Co-operative Research Programme) of OECD (Organisation for Economic Co-operation and Development). The author acted as a visiting researcher in Spain at IVIA (*Instituto Valenciano de Investigaciones Agrarias* – Valencian Institute of Agricultural Research). A web-based questionnaire was sent to over 200 selected recipients around the World using LinkedIn™. The recipients were members of EurAgEng (The European Society of Agricultural Engineers), FinAgEng (FinAgEng Maaseudun teknologia Ry - The Finnish Society of Agricultural Engineers), ASABE (the American Society of Agricultural and Biological Engineers), and CIGR (Commission Internationale du Génie Rural – International Commission of Agricultural Engineering). The respondents' competence profile was variable. They were strong in engineering, research and, most of them, also in practical use of technologies at the farm level. They were not experts in marketing or sales. As the questionnaire was challenging, it took almost an hour to answer it, only 41 complete replies were achieved. Thereafter 10 in-depth face-to-face interviews of selected experts were done. The interviews were made in Spain and Finland and the interviewees were originated from Spain, Israel, Denmark, and Finland. Webropol™ software was used for the questionnaire. The interviews were recorded and done as thematic (semi-structured) interviews (Hirsjärvi & Hurme 2001). The questionnaire and the interview had three main parts: assessing the current PF (Precision Farming) technology, the innovation in PF, and User-Centred Design (UCD) in designing PF technologies. The responders were asked to tell what they thought about UCD as a methodology to enhance innovation. The experts also prioritized the most important research and development topics of UCD in agricultural engineering. Finally, they rated the importance of related actions in research policy.

The second research project 'AgriSpin – Space for Innovations in Agriculture' (2015-2017), was funded by the Horizon 2020 research and innovation programme of European Union. In AgriSpin, there were 15 partner organizations from 12 European countries.
AgriSpin aimed to find efficient methods to enhance innovation. The goal was to explore ISSPs in agriculture and rural development. The overall goal was to help create a stimulating environment for innovations.
AgriSpin researchers applied and improved a Cross Visit Methodology that includes thorough analysis of innovation cases. In AgriSpin the analysis covered altogether 57 innovation cases in 15 countries in Europe. The Spiral of Innovation (Wielinga 2016, Fig. 1) was used to illustrate the cases and to communicate them to wider audience. For each case the research team arranged a Final Symposium where relevant stakeholders were informed about the findings. The stakeholders were challenged for developing the local innovation environment so that the speed of innovations in agriculture would be enhanced in the area.

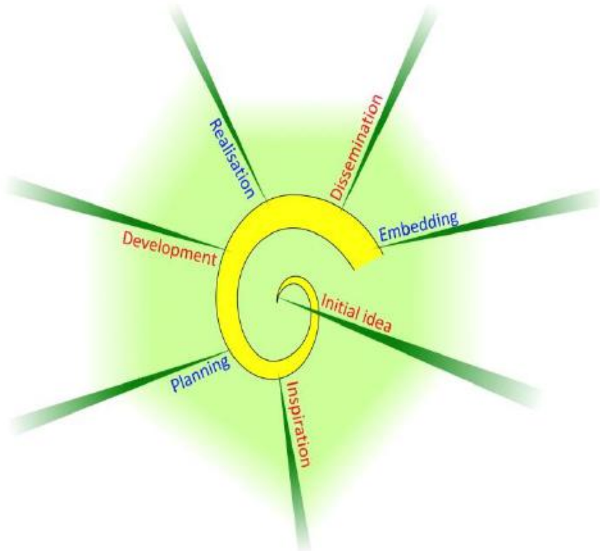

Fig. 1. Spiral of Innovations (Wielinga 2016).

Results and Discussion

The expert evaluations confirmed the proposed model for successful innovation (Haapala 2012, Fig. 2). According to the model, innovative technologies need first to be bought, and thereafter used in a proper manner so that their benefits are realized. Initially, in order to be bought, the buyers need to be convinced of the technical level of the technologies. The criteria of social and practical acceptability (as in Nielsen 1993) need to be fulfilled. User-Centred Design helps to create high-level, acceptable technologies and also helps the users to apply them. Thus, the use of UCD methodologies is seen as beneficial for the speed of innovation.
The experts agreed that the Schumpeterian real innovation model (Schumpeter 1912; Drejer 2004; McCraw 2010; Śledzik 2013) is required in agriculture. Innovative technologies and methods need to be spread and used by a wide user audience. According to expert evaluation, the most important obstacles for quick innovations are: lack of trust in new technology among farmers, bad usability of new technologies due to absence of User-Centred Design in the education of engineers and designers, omitting users in the innovation process. Thus, User-Centered Design (entrepreneur-driven in Schumpeterian theories) is considered as the key element for better acceptance of innovations.

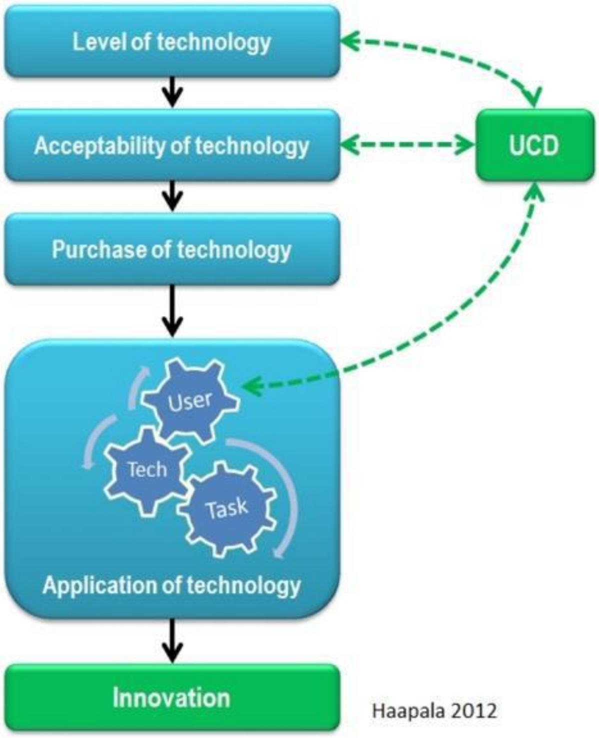

Fig. 2. Confirmed model of real innovation.

Most of the suggested topics for further research are concentrated around the user and his/her processes. Additionally, the elements of an effective user-centred R&D process, and the elements of highly acceptable solutions were prioritized (Fig. 3).

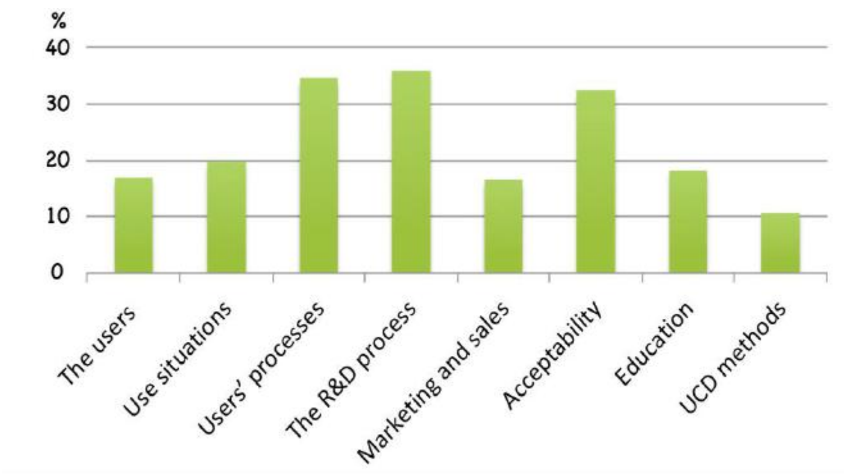

Fig. 3. Suggested topics for further studies.

The results of AgriSpin project were mainly methodological. The developed version of Cross Visit methodology (Wielinga 2016) enables the researchers, consultants, advisors and other actors to interact efficiently. The Spiral of Innovations was found to be an effective way to communicate. The Final Symposiums gave the participants a forum to reflect the findings immediately so that the final conclusions were accurate and the suggestions for the local actors were clear.
The main observations and suggestions from the 57 Cross Visits were:

- Besides economic and technological ones there were societal challenges limiting the acceptance of innovations in the cases;
- The successful cases had enjoyed multidisciplinary support for their innovation process;
- Free actors (independent, trustworthy and passionate individuals) had been important for the studied innovation cases.

Conclusions

Real innovation in agricultural engineering needs User-Centred Design (UCD) as a tool to make the solutions more acceptable for the users. The end-users decide to purchase new solutions or learn a new method or skill only if they consider their benefits high enough. Only realized benefits make the users return to buy again or to learn more.

The role of Innovation Support Service Providers (ISSPs) is crucial for efficient agricultural innovation. Supporting actions are needed: relevant services from advisory, research, consultation, authorities, and innovation funding. Relevant support speeds up innovation since it helps the innovators concentrate their efforts on the completion of the innovation process.

In order to be effective, the ISSPs need to have both in-depth knowledge and excellent co-operation skills in place. As the innovative solutions constantly get more complicated there is a growing need of specialized agricultural engineering consultancy. In addition, there is an urgent need for effective Multi-Actor Approach (MAA). The specialized advisors and consultants need to interact with each other, the end-users and other relevant stakeholders so that the MAA is realized and utilized to its full potential.

Innovation Brokers and Free Actors have a central role in future innovations, especially in the case of complicated systems level innovations, such as Precision Farming. To support the emergence of these services, funding needs to be available. Effective platforms for brokerage and operation of Free Actors need to be built.

Recruitment of Free Actors should be active and their role should be acknowledged as imperative for efficient innovation in agriculture.

The agricultural ISSPs should build better capacities for their professionals. Especially UCD and MAA methodologies should be learnt and practiced. These methods should be used throughout the innovation-supporting actions to make sure that the needed supporting elements are present in each phase of the innovation process. The available services should be easy to approach and preferably also physically near to the innovators.

Agricultural engineering professionals have the opportunity to take a leading role in the implementation of the needed ISSPs, in close co-operation with biological and economic specialists and related authorities and funders. Finally, close co-operation with innovative companies, entrepreneurs and end-users would be of great importance.

Acknowledgements

The author would like to thank OECD CRP (Co-operative Research Program) and EU Horizon 2020 program for funding and prof. Florentino Juste Perez for hosting him as a visiting researcher at IVIA.

WHY INVEST ON INNOVATIVE PRODUCTION? A QUALITATIVE EVALUATION OF THE EMERGING AVOCADO SECTOR IN CRETE, GREECE

Athanasios RAGKOS*, Georgia PAPOUTSI, Magdanili BARDOUNIOTI

Agricultural Economics Research Institute, Hellenic Agriculture Organization "Demeter", Athens, Greece
*Corresponding author: ragkos@agreri.gr

Abstract

Avocado is actually one of the most lucrative agricultural activities worldwide. Demand is rising rapidly relating to healthy diets and social status, while the increasing supply does not seem able to cope with it. Chania area in the Greek island of Crete has ideal climate and soil conditions to produce high quality avocados. As a result, orange trees are being eradicated and replaced by avocados. The purpose of this study is to provide a qualitative assessment of avocado production in Crete, in order to demonstrate under which prerequisites its growing trends will lead to overall sustainability (economic, social, environmental). The system is assessed by means of a SWOT analysis integrating considerations of actors across the value chain. The key finding is that the system requires synergies with other sectors but also close collaboration among stakeholders in order to achieve overall sustainability in the long term. Strategic design and collective actions are required towards this end.

Keywords: *Innovative production; Qualitative evaluation; Avocado.*

Introduction

Avocado production is a very dynamic and fast growing industry worldwide. In 2016, world production was 5.68 million ton., showing an overall increase of 24.6% from 2012 onwards. It is estimated that production will amount to 6.42 million ton. by 2020, with a respective estimated value increase by about $10 billion, from $13 billion in 2017 to $23 billion in 2027 (www.producereport.com).

Avocado has particular requirements for light soils, mild temperatures without large fluctuations and high quality irrigation water. For this reason, production is only feasible in specific areas globally. According to freshplaza.com, Latin America is the largest avocado producer in the world, valued at around $5.5 billion annually, with main centers in Mexico, the Dominican Republic, Chile and Guatemala. Production in North America is also significant in specific US states, such as California and Florida. In Africa, there has been systematic avocado production since the 1960s, particularly in Kenya, while on the Asian Pacific, New Zealand and China play an important role. For Europe and the Mediterranean, Israel is the most important producer (8.000ha), followed by Spain, which has elaborated high-level research regarding varieties and cultivation methods. The dominant avocado variety actually is Hass and represents more than 50% of production.

Global production is increasing every year, seeking to cover the rapidly increasing consumption. The incorporation of avocados into healthy diet programs, strong advertising and promotion, and generally the prevalence of a favorable consumption pattern related to lifestyles, contribute to this rising demand. The main market for avocados actually is Mexico, which hardly produces enough avocado to supply internal markets and cover its existing trade agreements. The USA is the second largest consumer, as in 2016, per capita consumption was about 3.5 kg of avocados per year, having doubled from 2006 to 2015. However, USA only produces a small portion of its needs and is dependent on imports from Mexico and other South American countries. This is largely the case for Asian countries as well, such as China and New Zealand, where production is mainly oriented to internal markets rather than international trade. In the EU, per capita consumption exceeded the threshold of 1kg per year just in 2017 and is constantly increasing (www.linkedin.com). Although European marketing channels are among the best organized worldwide, European production struggles to pace up with increasing demand and actually the EU is heavily dependent on imports. For instance, its main producer - Spain - has significant internal consumption and its production is mainly directed to the internal market, with only few exports, while in some periods massive quantities are imported to cover seasonal deficiencies. As a result, EU imports in 2016 exceeded 450 th.ton., with 90% originating from developing countries (Peru, Chile, South Africa, Kenya and Mexico) and the remainder being mainly covered by Israel (www.cbs.nl).

Due to its vast global potential, avocado production is associated with socio-economic changes and environmental pressures (Darnton, 2017). Speculation about short-term profits is common and often leads to adverse mid-term effects. Academic research on such issues is limited, however a review of relevant reports shows that avocado production is faced with increasing socio-economic problems, especially in developing countries. Recently, social instability, violence and other related issues were reported in the top avocado - producing country - Mexico (https://elpais.com/). Furthermore, avocado production is subject to numerous natural and market-related factors which increase fluctuations and bear increased risks (www.agroinsurance.com). For instance, the high income elasticity of avocado production shows that the production system is likely to be vulnerable to changes in international markets and the trade agreements with the EU and USA create serious commercial dependencies, despite being important sources of revenues for these countries. Another issue of importance is the increase in land prices, which limits the socioeconomic viability of avocado. It has been reported that land prices in Spain are increasing rapidly due to avocado, even rendering production unprofitable in the short run (www.freshplaza.com). According to Darnton (2017), social problems also arise relative to limited labor supply during intensive harvesting period, as the job is not at all alluring for occasional workers. In addition, extensive environmental problems, such as desertification and land degradation, have been reported in areas with intensive avocado monoculture, such as Chile and Mexico (phys.org, www.theguardian.com).

In this context, there are numerous opportunities for producers in global avocado markets. The Regional Unit of Chania in the Greek island of Crete, has the necessary soil and climate conditions that allow avocado production. Avocado plantations are being installed in the area for decades and the sector was quickly established as an industry with economic importance. However, responding to international developments, avocado is expanding in the area - in full production and/or new ones - much more rapidly than before. This implies a substantial change in the production pattern, in which citrus fruits - in particular oranges - prevailed until recently, also playing a very important role in socioeconomic development. Indeed, the structure of orange varieties permits production almost throughout the year, in contrast to the avocado production system, which exhibits significant fluctuations between years (alternate bearing) and seasonally (no production from June to October), and this created a credible and well-functioning value chain. Nonetheless, low producer prices for oranges have now led to a decrease and - combined with frequent disease outbreaks - to gradual substitution by avocado. Under this situation, marketing infrastructure is under-utilized and markets traditionally fed with Cretan oranges have already turned to other areas in Greece or abroad.

The organization of the avocado production system and of the respective value chain in Chania is endowed with significant elements of innovation and should be considered as such. The expansion of the activity in the area should be accompanied by targeted interventions that limit the environmental and socioeconomic impact of the transition while simultaneously securing long-term benefits for stakeholders. Therefore, strategic design is essential to accommodate endeavors to establish a new lucrative activity with development potential across the value chain.

The purpose of this paper is to provide insights regarding the proper interventions to render avocado production in Chania a viable agricultural activity with positive socioeconomic impact. For this reason, the paper presents a SWOT analysis of the sector, based on qualitative data from a survey of actors involved in the avocado sector in the area. The analysis seeks to demonstrate how interconnected internal and external factors should be considered simultaneously, in order to design integrated strategies at different temporal levels.

Material and Methods

The paper is based on a primary questionnaire survey which took place in Chania area in 2018-2019. Since data availability regarding the structure of avocado production in Greece (and in Chania) is scarce and not up-to-date, a probability sampling approach was not considered. A qualitative approach was thus preferred in order to collect information from a variety of actors across the avocado value chain or from other related stakeholders. Therefore, a questionnaire was designed in order to collect qualitative information regarding (a) the evolution and development of avocado production in Chania; (b) the history of the businesses (farms/nurseries/manufacturers) and their decision to get involved in the sector; (c) their main sources of information and advisory services available to farmers; (d) the problems that actors encounter in avocado production and marketing; (e) their plans for the future in avocado/orange production and marketing.

The questionnaire was addressed to actors in the avocado value chain in the area, including 20 avocado producers, 6 fruit industries, 1 nursery owner, 1 researcher, 2 representatives from local state institutions and four persons belonging to more than one categories (researcher/producer/nursery owner). The qualitative survey data were combined with other information found in relevant publications - although literature regarding the avocado sector in Greece is very scarce – or through informal discussions with other local stakeholders.

This information was systematically evaluated and was used in a SWOT analysis of the avocado sector in Chania. SWOT analysis (Strengths – Weaknesses – Opportunities – Threats) is one of the best-known strategic planning tools, widely used to analyze the internal and external environment of businesses, industries and markets (Hill and Westbrook, 1997; Jyothi et al., 2008). SWOT analysis captures aspects of the status-quo situation and examines the strengths (comparative advantages) and weaknesses associated with the internal environment as well as opportunities and threats in the external environment, that will need to be considered in future interventions, thus facilitating strategic planning.

Results and Discussion

Table 1 presents the SWOT analysis of the avocado sector in Chania. It is evident that there are complex issues in the internal and external environment that need to be considered simultaneously in order to understand the dynamics of the sector. Therefore, based on the SWOT analysis, several key points emerge.

Chania area has favourable soil and climate conditions for the production of high quality avocado. This has been shown since decades, when the cultivation started in specific parts of the Region. Since avocado is well adapted in Chania, it requires minimum agrochemical inputs and valorizes existing irrigation infrastructure. Nonetheless, the survey showed that only few farmers comply with 'best' production methods and that there is a wide variety of practices in fertilization (excessive use of inorganic nitrogen), weed management and, especially, in harvesting. Actually, several varieties are being successfully installed (mainly Hass varieties but also Pinkerton and Ettinger) together with existing Fuerte and Zutano plantations and this can accommodate a successful future pattern, by prolonging the production period, which will cover demand in markets almost throughout the year. This can be an important advantage, however, if producers have access to high-quality propagation material, which will demonstrate high adaptability and endurance to local conditions- (eg salinity, adaptability to various soil types etc.). This would also contribute to tackling disasters from extreme weather events, such as heavy rain and strong winds.

Table 1. SWOT analysis of avocado production in Chania, Crete, Greece

Strengths	**Weaknesses**
• Favourable soil and climate conditions • Important production and marketing infrastructure – "Cretan product" • Choice of varieties which permit a wider period of production and sales • Possibility to ensure high farm incomes • Low requirements in agrochemicals and crop interventions • Availability of farm labour	• Informal production and sales • Lack of central organization and strategic planning and low levers of cooperation • Low adoption of 'best' production practices and high variability • Low levels of scientific knowledge, lack of advisory services and information • Lack of integrated "Cretan avocado" identity
Opportunities	**Threats**
• Increasing demand – Emerging markets • Low proportion of European/global production • Multiple possibilities for certification • Niche markets – Alternative markets • Synergies with other activities and networks (e.g. tourism) • Contractual production • Research and development structures	• Competition from other European and Mediterranean countries • Higher national market prices that international prices – Low competitiveness • Low penetration in niche markets • No well-adapted propagation material • Climate change – Extreme weather events • Decline in orange production

A major issue is the high percentage of informal avocado production and sales. Orange trees are being replaced by avocados rapidly, without, in many occasions, this being formally declared to competent control bodies. Undeclared production is sold through informal channels, reaching the consumer without identity and, in some cases, with significantly lower quality than the branded product, at almost the same price. It is evident that all actors involved in informal value chains gain higher profits, however unfair trading practices will be detrimental for the whole system in the mid- and long-term, compromising the reputation of the Cretan product in markets. A side-effect of informal production is the increase of stealing avocados from plantations, although this phenomenon is not a problem only for Crete.

One of the main effects of informal production is the lack of strategic planning in avocado but also in the whole primary sector of the area. Any plan and proposal for avocado should be followed by adjustments to tackle this issue, which distorts the 'true' image of the sector and results in marketing problems, lack of product identification and irregural harvesting periods reflected in lower product quality. This is combined with a relatively low level of knowledge and of targeted scientific research on avocado production under the specific conditions of Chania, although the area has structures that could contribute to the improvement of knowledge. Cutting-edge research topics would include new varieties, diseases, other enemies and propagation material. In order to achieve this, a basic prerequisite is extroversion and close interconnection with farmers and businesses across the value chain. Nonetheless, farmers are skeptical concerning the role of research, institutions and the processing sector. The latter comprises well-organized and dynamic companies, but lack of trust does not allow to reach important markets abroad, which leads to lost opportunities. In this context, the lack of qualified advisory managers threatens the development of the system. There is a relatively low level of information among producers, asymmetric information among actors and – more

than often – false, exaggerated or deceitful information, yielding high expectations which avocado production in the area cannot uptake.
Avocado production can be a lucrative activity for farmers, as it combines important advantages: growing international demand due to the prevalence of a new consumption pattern for avocado, deficit in the national market and high product quality (under specific conditions). Actually, local producer prices are even 50% higher than international prices. In addition, Regional production is still low and even if it increases significantly it will only stand for a very small part of global production, which makes its marketing relatively easy through short or mainstream supply chains to markets such as Germany, Netherlands and, of course, Greece. The degree to which farmers will profit from these favourable conditions in the long run depends on how the value chain will adapt to accommodate the increasing supply. For instance, the low production volume also leads to losses of significant opportunities in international markets, which require the regular timely provision of high product quantities, unavailable under the current conditions in the production system. For a future increase in production, especially to the extent that the Greek market may become saturated, the sector should be expected to conform to international standards or else will not be able to reach competitive markets. A solution here could definitely be provided through contractual farming, which not only constitutes a way to increase overall market performance, but will also reduce risk and uncertainty for farmers and other actors in the value chain. The economic viability of avocado production is determined by other equally important parameters such as (a) low requirements for fixed and variable capital, (b) high importance of family labor and (c) availability of product at times when international supply is low, through the selection of suitable varieties.
By looking at the weaknesses - and even at some strengths - of Cretan avocado sector, it can be argued that the system has neglected its comparative advantages, sometimes presenting a non-coherent image in markets. The low level of production has so far exacerbated this problem, as there was no need to promote the product collectively or incorporate it into existing networks, value chains and quality schemes (eg "Cretan product", olive oil, tourism etc): avocados would 'sell themselves' effectively. Nevertheless, in the new situation which is anticipated, the standardization and certification of Cretan avocado combined with its high quality could be proven vital. In particular, certification of the production practices, with an emphasis on the agro-ecological character of the product and on its origin (PDO, PGI), could diversify the local product from the avocados of competing countries. In addition, certification of the product will be the "key" for Cretan avocado to access niche markets. Indeed, such markets are ideal for Cretan avocado as they (a) usually demand premium quality characteristics, (b) require relatively small quantities, (c) are interested in origin and production practices. Nonetheless, under the current conditions, the production system cannot approach such markets and this is highly due to the informal production and the lack of certification. This is a serious problem in a highly competitive market with rapidly growing production in competing countries such as Spain and Israel, with tradition, high level of innovation and availability of scientific knowledge and highly skilled staff.
Chania area has a healthy economic environment that attracts human resources. Labor availability is, therefore, an important asset for successful avocado production, as the sector is labor intensive. This is especially crucial for early varieties, as the harvesting period coincides with olives and some varieties of oranges. However, workers are rarely specialized or trained resulting in problems in fruit quality. Another related issue is undeclared labor, as almost all workers in avocado production are migrants who do not generally want to be declared officially. Apart from the obvious consequences, this issue is a problem for producers, as they cannot declare labor costs as expenses and should thus incur higher taxes. Increased production costs are a serious threat to the long-term viability of the sector, considering that

producer prices in the following period should adapt to international, if local produce is to access international markets.
Last but not least, special reference should be made to orange production. Although is a traditional activity with important infrastructure in the area and despite the fact that Cretan oranges are well-respected in markets, there was consensus that the sector is not profitable under current conditions and that this is largely due to lower demand in the internal market. However, orange production should be continued in Chania to reduce the risk and uncertainty associated with avocados, with interventions mainly related to the sale of the product and promotion, in order to redeem the market share of past decades. Existing technical knowledge, PDO certification, marketing networks and recognizable brand name are also important elements to support a promotion campaign for orange.

Conclusions

The avocado sector in Chania is fast developing, following an irrational pattern: selecting inappropriate soils and areas, planting of not well-adapted propagatin material, varying cultivation practices, lack of cooperation across the value chain. Under this form, avocado does not have the potential to support the local rural economy in the long run. The system requires to invest on quality and to develop an integrated strategic plan to approach niche markets in order to achieve higher prices, develop stable, trust-based trade relationships and reduce uncertainty. In the internal level, cooperation and coordinated activities are necessary to support sustainable development, in the form of the well-organized orange production system. It should be noted, however, that the expansion of avocado could bring environmental problems related to pressures on water resources, as relevant examples have already been identified abroad (eg Chile, Mexico) and have led to desertification.

Abstract

A robust institutional framework is necessary to turn into reality the ambition of the 2030 Agenda for Sustainable Development, which encompasses the Sustainable Development Goals (SDGs). This review paper analyses the institutional arrangements and governance mechanisms adopted in the Mediterranean countries for the implementation of the 2030 Agenda. It is mainly based on an analysis of the Voluntary National Reviews submitted by Mediterranean countries to the United Nations' High-Level Political Forum on Sustainable Development (HLPF) from 2016 to 2019. Basically, a variety of institutional arrangements have been used by Mediterranean countries with the aim of ensuring an effective and operational inter-ministerial coordination (cf. "whole-of-government" approach). In this respect, there are two types of institutional mechanisms: coordinating mechanisms at the highest government level (e.g. national committee under prime minister's or president's office) and implementation coordination by specific ministries (e.g. Ministry of Development in Turkey, Ministry of Foreign Affairs in Cyprus and Morocco, Ministry of Tourism and Sustainable Development in Montenegro). Some countries opted for the establishment of new structures (e.g. National committee for monitoring the implementation of SDGs in Egypt), while others use the institutional arrangements put in place for the Millennium Development Goals (MDGs). Apart from inter-ministerial coordination, these institutional arrangements also aim to ensure the "localisation" of the SDGs and their implementation at sub-national level (e.g. regional, local), increase the involvement of the legislative power and parliaments in the process, and improve the inclusiveness of and ownership by a wide range of stakeholders (e.g. civil society, private sector, academia). The achievement of the SDGs implies going beyond fragmented, hierarchical and "siloed" processes and cultures and working across institutional boundaries. Finally, this review provides evidence of good practices and helps to promote mutual learning among Mediterranean countries.

Keywords: *Sustainable Development Goals, Mediterranean region, institutional architecture, governance, coordination*.

Introduction

At the United Nations' Sustainable Development Summit of September 2015, Member States adopted the 2030 Agenda for Sustainable Development, with a set of 17 Sustainable Development Goals (SDGs) at its core (United Nations, 2015). The 2030 Agenda sets out ambitious and transformative goals to respond to the complex challenges facing humanity. The 2030 Agenda and the SDGs provide a universal framework for action to achieve sustainable development but recognize differences among countries in terms of challenges and resources (Fukuda-Parr et al., 2018). While the Millennium Development Goals (MDGs) targeted only developing countries, the SDGs are universal i.e. for both developed and developing countries. The wide-ranging and broad scope of the 2030 Agenda implies that to achieve the SDGs there is a need to strengthen linkages and coordination both horizontally, among ministries/sectors, and vertically, among government levels. Moreover, the 2030 Agenda commits stakeholders to work together to promote social development, environmental protection and inclusive economic growth. Indeed, the achievement of the 2030 Agenda and the SDGs requires substantial and sustained commitment and cooperation of various stakeholders (United Nations, 2015). Therefore, establishing and/or strengthening existing governance and institutional frameworks is fundamental for the implementation of the 2030 Agenda. Indeed, even many developing countries need to strengthen and expand existing institutional mechanisms used for the implementation of the MDGs to suit the coordination and monitoring requirements of the 2030 Agenda, which is much broader and comprehensive than the MDGs (UN-DESA, 2016).

This review paper analyses governance mechanisms and institutional arrangements adopted in the Mediterranean countries for implementing the SDGs. The paper addresses several issues: type and form of the adopted governance mechanism; horizontal coordination mechanisms between the established high-level coordination unit and other public institutions; support of the established high-level institution by technical bodies; mechanisms to ensure the legislative and parliamentarian follow-up of the SDGs; processes of vertical institutional coordination and "localisation" of the 2030 Agenda.

Material and Methods

The geographical coverage of the review is similar to that of the Mediterranean Strategy for Sustainable Development (UNEP/MAP, 2005, 2016) including 11 Northern Mediterranean Countries (Albania, Bosnia and Herzegovina, Croatia, Cyprus, France, Greece, Italy, Malta, Montenegro, Slovenia and Spain) and 10 Southern and Eastern Mediterranean Countries (Algeria, Egypt, Israel, Lebanon, Libya, Morocco, Palestine, Syria, Tunisia and Turkey).

The paper is based on a desk review of recent academic and expert literature from different sources. The main sources of information were the Sustainable Development Knowledge Platform and the Sustainable Development Solutions Network. From the former, data were mainly collected from the Voluntary National Reviews (VNRs) of Mediterranean countries and the syntheses of VNRs submitted in 2016 (UN-DESA, 2016), 2017 (UN-DESA, 2017) and 2018 (UN-DESA, 2018). From the latter, data were collected mainly from the SDG Index and Dashboards (Sachs et al., 2018; Sustainable Development Goals Center for Africa & Sustainable Development Solutions Network, 2018). Moreover, a desk review of scholarly literature (e.g. Allen et al., 2018) was carried out. The VNRs are a central element of the follow-up and review mechanisms of the 2030 Agenda (Fukuda-Parr et al., 2018; United Nations, 2015). Out of the 21 Mediterranean countries, five (Egypt, France, Montenegro, Morocco, Turkey) submitted their VNRs in 2016, three (Cyprus, Italy, Slovenia) in 2017, six (Albania, Greece, Lebanon, Malta, Spain, Palestine) in 2018, and five (Algeria, Bosnia and Herzegovina, Croatia, Israel, Tunisia) in 2019, while no VNRs are planned by Libya and Syria, due to unrest situations in both countries. Meanwhile, Egypt (2016, 2018), France (2016, 2019) and Turkey (2016, 2019) submitted twice their VNRs.

The main limitation of the present study is that the scope of the analysis is mainly limited to the content of the VNRs submitted by Mediterranean countries in the period 2016-2019 and, thus, reflects official opinions of these countries without much further cross-validation. It should also be highlighted that VNRs submitted in 2017, 2018 and 2019 provide more details than those submitted in 2016 (first year of SDGs implementation), which implies that comparison might has been biased towards countries submitting recently their VNRs.

Results and Discussion

Most of countries have adopted a *three-tier implementation approach* to achieve coordination and coherence in the landing of the SDGs (UN-DESA, 2018):

- The *first tier* is typically concerned with strategic national priorities and policy direction, and the integration of global frameworks and commitments (UN-DESA, 2018). In general, countries have some high-level entity or mechanism – which in most cases already existed prior to the 2030 Agenda adoption – that makes political decisions on the country's priorities, vision and development frameworks through which to implement the 2030 Agenda (UN-DESA, 2017).
- The *second tier* typically carries out coordination among government agencies and line ministries and addresses strengthening their capacity to implement the SDGs (UN-DESA, 2018). The first two tiers represent a decision-making level that defines how the country can achieve coherence in the implementation of the 2030 Agenda and they are usually coordinated by the offices of the president/prime minister (PM), or a coordinating ministry/body that is directly responsible to the president/PM or a high-level council (UN-DESA, 2017).
- The *third tier* deals with coordination of technical work, thus involving both government and non-state stakeholders (UN-DESA, 2018). This tier has, often, working groups to deal with sectoral issues where experts provide evidence and advice on different implementation areas and aspects to inform the decision-making tiers (UN-DESA, 2017).

As in other countries and regions (Anonymous, 2018c; UN-DESA, 2016, 2017, 2018), a variety of institutional arrangements have been used by the Mediterranean countries for the implementation of the 2030 Agenda. The utmost aim of these arrangements is to ensure an operational inter-ministerial coordination (cf. "whole-of-government" approach) as well as an active involvement of a wide range of stakeholders (cf. "whole-of-society" approach). The emphasis on integration and coordination is an important feature of many of the institutional mechanisms and frameworks (UN-DESA, 2016, 2018) and high-level political support is highlighted as important to coordinate and mobilize public institutions (UN-DESA, 2016). Therefore, coordination mechanisms are often connected to and under the supervision of the offices of presidents or prime ministers (Albania, Egypt, France, Greece, Italy, Israel, Lebanon, Palestine, Slovenia, Spain) (Anonymous, 2016b, 2017, 2018c, 2019a; General Secretariat of the Government – Greece, 2018; Italian Ministry for the Environment, Land and Sea, 2017; Ministry of Planning Monitoring and Administrative Reform - Egypt, 2018; State of Palestine, 2018; UN-DESA, 2018). In some countries, the inter-ministerial committees on the SDGs are chaired by the PM, led jointly by two ministries, or by one ministry (Anonymous, 2018c; UN-DESA, 2018). In other countries, specific ministries were designated to coordinate the 2030 Agenda implementation (UN-DESA, 2016, 2018).

Most institutional arrangements and frameworks involve numerous relevant institutions and ministries, including those addressing economic growth, social and employment sectors, environment/natural resource management (UN-DESA, 2016, 2018). *Egypt* established in 2015 a new entity, the National Committee for Monitoring the Implementation of the Sustainable Development Goals, to coordinate and follow up the implementation of the SDGs (Anonymous, 2016a; Ministry of Planning Monitoring and Administrative Reform - Egypt, 2018). The Committee is under the direct supervision of the PM and is composed of representatives of 17 ministries and state entities (Anonymous, 2016a). In *Lebanon*, the Council of Ministers established in 2017 a National committee to oversee and guide the roll-out of the SDGs. The committee is chaired by the PM and involves more than 50 director-general officials (Anonymous, 2018a; UN-DESA, 2018). In *Greece*, the General Secretariat of the Government (GSG) – especially the Office of Coordination, Institutional International and European Affairs – plays a central role in the inter-ministerial coordination and governance of the implementation of the SDGs. The GSG coordinates the activities of the Inter-Ministerial Coordination Network for the SDGs (established in December 2016 and including all line ministries), the Economic and Social Committee of Greece (a national multi-stakeholder consultation platform), Hellenic Parliament as well as the Hellenic Statistical Authority (General Secretariat of the Government – Greece, 2018; UN-DESA, 2018). In *Albania*, the Inter-Ministerial Committee on the SDGs, chaired by the deputy PM, ensures coordination and leadership of the process (Council of Ministers - Republic of Albania, 2018). *Croatia* established the National Council for Sustainable Development for implementing the SDGs (Anonymous, 2019b). In *Italy*, the Presidency of the Council of Ministers took the lead in coordinating and managing the National Sustainable Development Strategy 2017-2030 (NSDS), that is aligned with the SDGs (Italian Ministry for the Environment, Land and Sea, 2017). *Malta* set up the Focal Point Network – under the Ministry for the Environment, Sustainable Development and Climate Change – that involves a senior representative from each line ministry and meets periodically (Anonymous, 2018b). *Palestine* established a National SDG Team, under the overview of the PM's office, to lead the implementation of the SDGs (State of Palestine, 2018). In *Slovenia*, the Permanent Inter-Ministerial Working Group on Development Policies – coordinated by the Government Office for Development and European Cohesion Policy – assumes a leading role in SDGs coordination mechanism. It was established in 2017 and is composed of two representatives from each ministry that also serve as focal points at their ministries (Anonymous, 2017). The Government of *Spain* created the figure of a High Commissioner for the 2030 Agenda, who will report directly to the President of the Government (i.e. PM). It also created a High-Level Group (HLG) for inter-ministerial coordination where all levels of government (e.g. ministries, Autonomous Communities, local governments) are represented (Gobierno de España, 2018). *Tunisia* created a National technical committee on the 2030 Agenda that is led by the Ministry of Development, Investment and International Cooperation (MDICI), and the Ministry of Foreign Affairs (Anonymous, 2019c). In *Turkey*, the National Sustainable Development Commission (NSDC) – established in 2004 under the Ministry of Development – serves as the central political body in the follow-up of the SDGs (Ministry of Development – Turkey, 2016).

Countries are mandating different *ministries* as overall coordinators of the SDGs implementation. The importance of leadership by a government ministry with sufficient political power (e.g. planning and sectoral lead ministries) as well as some degree of control over financial resources (cf. finance ministries) is highlighted (UN-DESA, 2016). Examples in Mediterranean countries include key ministries such as the Ministry of Development (Turkey), Ministry of the Environment, Energy and Sea (France), Ministry of Foreign Affairs and Cooperation (Morocco), Ministry of Foreign Affairs and Trade Promotion (Malta), Ministry of Tourism and Sustainable Development (Montenegro). In *Lebanon*, the "4Ps" thematic groups of the National committee on SDGs are coordinated by different ministries and state institutions; Ministry of Public Health for "People", Ministry of Environment for "Planet", Ministry of Economy and Trade for "Prosperity", Office of Minister of State for Administrative Reforms for "Peace" (Anonymous, 2018a). In *Cyprus*, while the implementation of the whole 2030 Agenda is under the coordination of the Ministry of Foreign Affairs; a relevant line ministry has been assigned as coordinator for each of the 17 SDGs (Ministry of Foreign Affairs - Cyprus, 2017). For promoting SDG ownership within the government, some countries established specialized *SDG units* or *focal points* in line ministries (Anonymous, 2018c). In *Egypt*, the national SDGs committee is complemented by sustainable development units and working groups within line ministries (Anonymous, 2016a; Ministry of Planning Monitoring and Administrative Reform - Egypt, 2018).

High level committees and institutions are often supported by *technical bodies*. Several countries (e.g. Croatia, Egypt, Italy, Morocco, Turkey) reported that their statistical offices are members of the coordination mechanisms or provide them with technical support especially regarding monitoring. Technical and expert committees as well as advisory boards

and panels have been set up in some countries to integrate the SDGs into the mainstream agenda. In *France*, a multidisciplinary committee of international experts was set up to capture the systemic nature of the SDGs in the development of the next national action plan (Anonymous, 2016b). In *Turkey,* a task force of experts, within the Ministry of Development, has been assigned to integrate the SDGs into national development plans (Ministry of Development – Turkey, 2016; UN-DESA, 2016). In *Albania*, technical support to the Inter-Ministerial Committee on the SDGs is provided by the SDG Inter-Ministerial Technical Working Group and the UN agencies (Council of Ministers - Republic of Albania, 2018).
Governance arrangements such as inter-ministerial committees provide coordination and leadership, sometimes drawing on *non-state stakeholders* (Anonymous, 2016b, 2017, 2018c, 2019a, 2019c; General Secretariat of the Government – Greece, 2018; Gobierno de España, 2018; Italian Ministry for the Environment, Land and Sea, 2017; Ministry of Development – Turkey, 2016; Ministry of Foreign Affairs and Cooperation – Morocco, 2016; State of Palestine, 2018; UN-DESA, 2018). Apart from line ministries, national committees on the SDGs also include other authorities and bodies and, sometimes, representatives of the civil society and private sector. For instance, in *Egypt*, the Central Authority for Public Mobilization and Statistics, the National Council for Motherhood and Childhood, and the National Council for Women are also members of the National committee on the SDGs (Anonymous, 2016a; UN-DESA, 2016). In *Lebanon*, the National committee to oversee the roll-out of the SDGs includes representatives of the private sector and civil society to promote a participatory, open and inclusive approach (Anonymous, 2018a; UN-DESA, 2018). In *Albania*, the Inter-Ministerial Committee on the SDGs involves, besides key government institutions, stakeholders from the civil society, business community, academia and international organisations (Council of Ministers - Republic of Albania, 2018). In *France*, the civil society, private sector and general public as well as their representative bodies (e.g. National Council for Ecological Transition; National Council for Development and International Solidarity; Economic, Social and Environmental Council) are actively involved in the implementation of the SDGs (Anonymous, 2016b). The National SDG Team in *Palestine* is supported by 12 working groups – each tasked with one or different SDGs – that involve different stakeholders (civil society, private sector, workers' union, women organizations, youth organizations, academic and research institutions) (State of Palestine, 2018).
In the context of decentralisation, it is widely recognised that effective *vertical integration* is needed to facilitate the "*localisation*" of the 2030 Agenda (UN-DESA, 2017, 2018). Many countries established structures that link national with sub-national (regional, cantonal, local) governments to strengthen their capacity to implement the SDGs (UN-DESA, 2017, 2018). Such structures have an added value in countries with a federal system (UN-DESA, 2017) e.g. Bosnia and Herzegovina that consists of the Federation of Bosnia and Herzegovina, Republika Srpska and Brčko District. Indeed, a number of strategies and mechanisms are being undertaken by national governments to connect, engage and build capacity of local and sub-national governments (Anonymous, 2018c; UN-DESA, 2016). In *Spain*, sub-national governments (e.g. 17 Autonomous Communities / regional administrations, Federation of Municipalities and Provinces of Spain) are actively participating in national decision-making and decentralised SDGs implementation. For instance, the government of the Autonomous Community of Andalusia adopted the Andalusian Sustainable Development Strategy 2030 (EADS 2030) (Gobierno de España, 2018; UN-DESA, 2018).
Countries also report the involvement of *parliaments* through actions such as establishing working groups for the legislative follow-up of the SDGs (Anonymous, 2018c), so that they can exert their vital legislative and oversight functions, including budget adoption (UN-DESA, 2016, 2017, 2018). Some parliaments are represented in the institutional and

coordination frameworks to implement the 2030 Agenda and/or have the SDGs integrated in their activities (UN-DESA, 2016). Many Mediterranean countries (e.g. Albania, Cyprus, Egypt, Greece, Montenegro, Slovenia, Spain) emphasized the importance of engaging parliaments and members of parliaments (MPs) in the whole implementation process. The parliament reviews reports on the SDGs in *Montenegro* (Ministry of Sustainable Development and Tourism – Montenegro, 2016; UN-DESA, 2016). In *Lebanon*, the SDG parliamentary committee mapped existing legislation against the 2030 Agenda and ensures follow-up of progress towards the SDGs (Anonymous, 2018a; UN-DESA, 2018). In *Cyprus*, the House of Representatives' Committee for the Environment monitors and review Cyprus's progress in SDGs achievement (Ministry of Foreign Affairs - Cyprus, 2017). In *Spain*, the Joint Parliamentary Committee for the 2030 Agenda (with members from the Senate and the Congress of Deputies) monitors the implementation of the SDGs. The Action Plan for the Implementation of the 2030 Agenda in Spain foresees holding an annual plenary session to monitor progress made on the 2030 Agenda (Gobierno de España, 2018).
Institutional frameworks are among the major *challenges* for the implementation of the 2030 Agenda (Allen et al., 2018; UN-DESA, 2016, 2017, 2018). Indeed, challenges include insufficient coordination and communication between ministries and agencies dealing with sustainable development; and fragmentation of responsibilities and mandates for SDGs implementation (UN-DESA, 2016). *Turkey* highlighted that many institutions still have 'siloed' processes and hierarchical cultures, noting that coordinating efforts across institutional boundaries and sectors is a real challenge (Ministry of Development – Turkey, 2016). *Montenegro* (Ministry of Sustainable Development and Tourism – Montenegro, 2016) emphasized that "*Institutional coherence and alignment of sectorial policies and responses should be interwoven into the everyday activities of competent bodies and institutions at the local and national level, as well as of the entities outside public administration system*" (p. 127). Countries also noted insufficient harmony and coherence between national and sub-national (regional, provincial, local) levels of government and, generally, lack of capacity at local government level (UN-DESA, 2016). Also *Albania* identified the strengthening of the institutional capacities of all key stakeholders engaged in the SDG implementation process as one of the main challenges to be addressed (Council of Ministers - Republic of Albania, 2018). Meanwhile, *Croatia* highlighted the need to further develop and improve the institutional setup with well-defined organization, coordination and control structure (Anonymous, 2019b).

Conclusions

This paper undertook an analysis of the Voluntary National Reviews submitted by the Mediterranean countries in the period 2016-2019 to highlight governance mechanisms and institutional arrangements put in place to ensure a smooth and effective implementation of the 2030 Agenda for Sustainable Development. The analysis aimed to pinpoint key aspects that may require special attention and to highlight good practices and valuable experiences that could be utilized to promote mutual learning and share learned lessons in the Mediterranean region and beyond. In general, substantial progress was reported by Mediterranean countries in strengthening existing and/or establishing new institutional and governance frameworks. However, while achieving the 2030 Agenda requires governments to work across policy areas, institutional set-up still presents a major challenge in the implementation of the SDGs for many Mediterranean countries. Therefore, institutions in several Mediterranean countries need further strengthening to be able to formulate coherent governance frameworks that allow for different government agencies and bodies, especially ministries, as well as the different levels of governments (central/national, regional, provincial, local) to work together to ensure an effective and efficient implementation of the SDGs. It is clear that the success of the SDGs

– and the transformative agenda inspiring them – will depend on institutions overcoming 'siloed', hierarchical and fragmented processes and cultures and working across institutional boundaries in close collaboration with the civil society, private sector and academia.

CONTRIBUTION OF GRASSROOTS INITIATIVES TO SUSTAINABLE URBAN FOOD SYSTEMS: THE CASE OF A CAMPUS GARDEN IN MUENSTER, GERMANY

Janina WITTENBERG[1], Hamid EL BILALI[2*], Carola STRASSNER[1]

Abstract

Cities depend on a constant food supply from the outside. Current challenges (e.g. climate change, soil depletion, biodiversity loss) and their interrelatedness with modern, industrialised food production may compromise future food security for millions of urban dwellers. Evidence shows that grassroots initiatives can foster transition towards resilient and sustainable urban food systems. This research contributes to the literature on grassroots initiatives and their role in sustainability transitions by analysing the urban gardening project campus garden GrüneBeete e.V. in Muenster. Semi-structured interviews with key informants from the initiative served as a basis for the analysis that was conducted according to an integrated sustainability transition framework. The analysis was performed along the three elements of the Multi-Level Perspective, i.e. niche, regime and landscape. Potential leverage points for transition, sustainability dimensions the initiative touches and its impacts were also studied. Special attention was devoted to social practices in educational and communal spheres. Urban gardening can be considered as a radical niche that aims to create an alternative urban food system. However, the analysed initiative has developed anchoring mechanisms with the regime institutions. Therefore, campus garden GrüneBeete e.V. is rather a symbiotic niche that, nevertheless, has the potential to induce a cumulative, incremental transformation in the regime. The main levers of change used by the initiative are raising awareness and spreading knowledge. In doing so, the campus garden impacts different dimensions of sustainable food systems (environmental, human, social, cultural, political, economic/financial). While the initiative is still small, it has a high upscaling potential given the favourable institutional and political landscape in Muenster and Germany at large. Urban gardening can be identified as a growing, but rather regime-compatible niche, one main strength being its potential impact on society's beliefs and value systems, and fuelling sustainability transitions through influencing social practices.

Keywords: *urban gardening, sustainability transitions, urban food systems, grassroots initiatives, food security*.

Introduction

For the first time in human history, more people are living in cities than in rural areas (Stierand, 2013). Activities in cities worldwide, directly and indirectly, are the most powerful drivers for global environmental problems, e.g. climate change, soil depletion, and biodiversity loss (WGBU, 2016). Modern agriculture and industrialised food production play a major role in these developments (cf. Clark & Tilman, 2017; FAO, 2019; WGBU, 2016). Cities depend highly on global markets to fulfil their demands, which – along with the aforementioned environmental changes – entail a growing vulnerability and unpredictability with regard to food security (Olsson, 2018). Other challenges play a role in this as well, like fair distribution and access to food, unhealthy diets, or the loss of nutritious value due to the way we prepare and process food. To combat all these problems, our food systems will have to change.

As complex systems are prone to inertia (Unruh, 2000; Walker, 2000), the necessary change is often difficult to achieve. Therefore, the body of research on sustainability transitions has been growing fast over the last decade (STRN, 2010; STRN, 2019). With the above-mentioned problems being closely intertwined with societal challenges, changes are particularly necessary in key areas of human activity (STRN, 2010). One topic of interest has been the role of civil society in driving those changes, and that of grassroots innovations in particular (Gernert, et al., 2018; Smith, et al., 2014; Seyfang & Smith, 2007). As their potential has not yet been sufficiently studied, it is still a relevant research object in this field (STRN, 2019).
Prior research has been conducted on grassroots initiatives in the foodshed of Muenster, Germany, in the research project "Sustainability Transitions and Food Security" of the Muenster University of Applied Sciences (MUAS) and the University of Natural Resources and Life Sciences, Vienna. Local initiatives have been mapped and their role in the transition towards a sustainable urban food system has been studied in this project (cf. Gernert, 2018). One of these initiatives is the campus garden GrüneBeete e.V.
The campus garden, situated on the grounds of MUAS, started as a student project at its Department of Food – Nutrition – Facilities in 2013, but is open to everyone interested. The registered association GrüneBeete e.V. was founded in 2014. Seeing urban gardening as a growing niche with transformative potential (WGBU, 2016), a case study of GrüneBeete e.V., an urban gardening project in Muenster, has been conducted in this research, the primary research question being: How does urban gardening contribute to the transition towards a sustainable urban food system?

Materials and Methods

To be regarded as relevant to the superordinate research project, initiatives had to fulfil four predefined criteria: they had to have voluntary initiative character (i.e. a group with two or more participants as opposed to single person or commercial actors), to be active within the foodshed of Muenster (i.e. located in or around the city), to have a focus on food and/or agriculture, and to be in existence for at least two years. GrüneBeete e.V. was one of six initiatives meeting the criteria, and the only urban gardening project among them.
The initiative was further examined using desk research and a first qualitative, semi-structured interview with key informants. This qualitative research method was chosen based on a reflexive, constructivist research paradigm which draws on the presumption that reality is individually and socially constructed rather than objective (Göpel, 2016; Kornmeier, 2007). An interview guide based on "W" questions was prepared and used as orientation in order to structure the interview. The interview took place on 7th November 2017 after one of the weekly official initiative meetings and lasted for about an hour. Two interviewers and two initiative members were present. One of the interviewees has been a member of the association since 2014 (i.e. since it was founded) and is involved in project organisation and as a tutor for classes in cooperation with MUAS, the other joined more recently in 2017.
Building on prior information, another semi-structured expert interview was conducted. The interview with two members of the initiative and registered association GrüneBeete e.V. took place on 15th May 2019 and lasted one and a half hours. One of the interviewees was involved in the managing committee and in creating a cookbook for the garden and actively represents it during the Muenster Sustainability Days and at the currently forming food policy council in Muenster. They joined the initiative in 2015 and 2016.
An interview guide that is based on the "Beacons of Hope"[14] checklist and questionnaire was developed for an earlier case study of one of the selected initiatives and served as a basis for

[14] The "Beacons of Hope" project at the University of Natural Resources and Life Sciences in Vienna was commissioned by the Biovision Foundation and funded by the Global Alliance for the Future of Food.

the interview. The collected data was therefore coded and portrayed according to an integrated analytical framework for analysing food system sustainability transitions that was developed in the "Beacons of Hope" project and further explained by El Bilali and Probst (2017). The framework uses the three elements of the Multi-Level Perspective, i.e. niche, regime, and landscape, as a basis. In addition, it incorporates elements of other relevant transition frameworks (e.g. Transition Management, Strategic Niche Management) to analyse food systems distinctly and assess the type of transition path taken as well as its transformative potential. To identify levers of change, niche-regime and regime-regime interactions are examined, studying how the niche anchors in the current regime and how it gains legitimisation. As for transition pathways, El Bilali & Probst refer to the classification of Geels & Schot (2007) into transformation, technological substitution, reconfiguration, de-alignment and re-alignment. To assess the transition impacts an initiative has, the desirable system state has to be defined as well as the initiative's effect on the different sustainability dimensions (environmental, human, social, cultural, political, financial and physical).

Results and Discussion

The campus garden GrüneBeete e.V. was founded in 2012 by two master degree students of the MUAS department of Food – Nutrition – Facilities as a semester project. For this reason, the land necessary for maintaining the garden is made available by the University. Over time, the project expanded, and to facilitate organisational tasks and ensure continuity for the project, the registered association was founded in 2014. During the spring-summer months, the initiative meets twice a week for gardening activities, and throughout the year it participates in city events. Despite its close connection to MUAS, the initiative emphasises its autonomy and independence from institutions to facilitate self-organisation and empowerment. It is not the initiative's vision for the garden to grow much further, but to spread the idea and set an example for alternative concepts while increasing quality of life for the individual. A main focus lies on the community aspect, and participation in urban development processes plays a role as well.

As a *niche*, the campus garden presents an alternative to incumbent *regime* structures with its outsourced food production in cities and the consequential alienation of citizens from nature and the way food is grown. In the Muenster region, agriculture is aligned to cater to global markets instead of regionality, with only 6% of agricultural produce being distributed via direct marketing (Lammers & Becker, 2014). Producers and consumers have become anonymous, and the interviewees deplore that food is something bought at the supermarket that has to be cheap, fast and convenient. By contrast, the community aspect and spatial proximity of the initiative create trust, which in turn is the basis for relatedness (Stierand, 2013). It offers room for exchange regarding experiences, knowledge, and cultural aspects, and also provides opportunities to integrate knowledge from the outside (i.e. through workshops, literature and seminars). Instead of conventional farming methods that are predominant in the region and modern agriculture in general, the gardening activities are based on organic farming principles (i.e. health, ecology, fairness, care) and value cycles.

While it does not have a direct influence on rules and institutions, the initiative fulfils three of the four criteria for alternative food systems (cf. El Bilali, et al., 2017): it reduces the distance between producer and consumer by merging the two roles in a local, small-scaled endeavour (space attribute); it gives food time to grow and be prepared with care (time attribute) and relies on organic and circular farming techniques (integration). Furthermore, in contrast to usual regime rules, none of the members own a patch in the garden, but everything belongs to everybody and everybody is responsible. As part of a national urban gardening movement, GrüneBeete e.V. contributes to pioneering activities that aim to spread the idea within an existing regime while the status quo is still relatively unaltered.

With regard to *landscape*, mega trends like individualisation and urbanisation are shaping today's society (WGBU, 2016), while at the same time, global threats like climate change and biodiversity loss have been entering the public debate. Recent developments (e.g. school strikes for the climate or the remarkably hot, dry summer) have fuelled this trend even further, especially in Muenster as winner of the German Sustainability Award in 2018. Where these developments are answered with a growing need for community and togetherness as well as a sensitisation towards environmental problems, landscape pressures arise. With individualisation as another mega trend, the DIY[15]-movement as a counter-trend draws people to urban gardening movements as well.
When asked about potential *levers of change*, the initiative members' top answer was raising awareness and spreading knowledge. However, the translation of knowledge into actual practices remains a main factor in unsustainable lifestyles. Ecological experiences play a crucial role in this (Frantzeskaki, et al., 2017). Therefore, appreciation for food and nature is increased through hands-on experiences in the garden, and the reproduction of routines that keeps incumbent social practices alive might thus be disrupted. The initiative seeks to incorporate experiential learning into formalised education as well, e.g. by collaborating with MUAS or by helping to set up gardens in primary and secondary schools in Muenster. The city of Muenster actively seeks the initiative's help in these endeavours. The garden is defined in its Articles of Association as a promotor of education, offering skilled support, workshops, and collaborations with Muenster's universities. According to Meadows (1999), one of the mightiest leverage points is changing the underlying paradigm inherent in the system. Social practices are closely interrelated with this paradigm, and initiatives like GrüneBeete e.V., through influencing these practices and the underlying views and values, might potentially fuel a paradigm shift, paving the way for more sustainable food systems.
The main form of *anchoring* for the initiative is the creation of networks. It puts a great emphasis on collaborations, and while the garden benefits from the support it gets from the city of Muenster and other local actors, it is at the same time a source of information and a potential partner for questions that arise in the context of other gardening projects, creating interdependencies. The initiative gains legitimacy through its status as a registered association (i.e. "e.V.", *eingetragener Verein*). Because of its close connection to the MUAS, the initiative often gets inquiries for research projects, and it is also part of a greater network of urban gardening initiatives ("*die anstiftung*") that supports research into the topic.
It is assumed that incremental change will not suffice to cope with sustainability challenges in urban food systems (e.g. Gernert, et al., 2018). Indeed, for the activities mentioned above, a certain degree of conformity and formalisation is needed. However, even as a symbiotic niche, urban gardening projects like GrüneBeete e.V. might change regime insiders' perceptions, resulting in new regimes through cumulative adjustments (cf. transformation path according to Geels & Schot, 2007). Additionally, the adoption of niche innovations might trigger further adjustments within the regime and the integration of further niche innovations (cf. reconfiguration pathway, Geels & Schot, 2007).
As is the case for the campus garden, collaborations with institutions constitute the predominant context for grassroots initiatives in Northern Europe (Sanna, 2018). This regime compatibility might render a niche less radical, resulting in incremental rather than transformative change. However, it is important to keep in mind the bigger picture: Urban gardening projects are just one of many niche innovations that act in concert to reach the same goals. It might not be able to feed the urban population, but it promotes a form of direct contact of people with nature and food production that has long been lost. The community aspect of communal gardens may strengthen the individual's identification with the local area,

[15] Do It Yourself.

and in combination with participative, democratic structures, contribute to forming a sense of responsibility. Additionally, it adds to individual (and consequently communal) wellbeing. This creates a context that facilitates learning and personal reflection. Together with the initiative's self-conception as a place of social learning, consumption practices of its members might become more sustainable, especially in initiatives like GrüneBeete e.V., which explicitly focuses on sustainable gardening techniques. Consumption practices play a crucial part in the transition to sustainable food systems, seeing as feeding the world on organic agriculture seems possible provided that consumption patterns change (Muller, et al., 2017).
Despite scholars identifying contradictions in regime institutions – which are embedded into the incumbent regime paradigms – collaborating with initiatives that follow a de-growth and sustainability transition narrative (Sanna, 2018), collaborating with MUAS has contributed to the initiative's stability without compromising its autonomy. This leaves room for debate over how reasonable it is to categorically deny grassroots initiatives their transformative potential when working symbiotically with the regime, and if a niche needs to be radical to have an impact. Smith et al. (2014) point out that this kind of dismissal might be premature, considering that each response to challenges by grassroots movements "create forms of knowledge of considerable social value in debates about innovation policy." Moreover, it can be argued that the initiatives need not necessarily demand radical system change, as "gradual steps of modernization might very well carry the potential for a fundamental transformation as well" (Adloff & Neckel, 2019, p. 8). This can constitute a valuable contribution to public discourse, and the more initiatives sow the seeds, the closer a society may get to reaching a critical mass.
Ultimately, the desirable system state the initiative strives for is a sustainable urban food system for the city of Muenster which takes ecological, social and economic factors into account. The impact an initiative may have in fostering such a transition increases the more dimensions are driven towards sustainability (El Bilali & Probst, 2017). GrüneBeete e.V. acts in the *environmental* dimension by making use of ecological farming methods and aiming at circular value production, and it increases *resilience capacity* by promoting biodiversity. The initiative's focus on education and development of knowledge and skills individually and as a community plays a role in the *human/creative* dimension. The *social/equity* dimension is influenced by the garden's communal, democratic structure and its aim to provide people in the city with access to a garden. The garden puts a great emphasis on the *cultural* aspect: It aims to conserve old cultivars and gardening techniques, and it promotes cultural exchange, e.g. in the form of a gardening project with refugees. While the initiative itself is not *politically* active, there have been group trips to demonstrations supporting sustainable agricultural policies. At the *financial* level, there is a direct effect on the members' disposable income as the harvest adds to their food supply, and regional value generation is promoted. As the initiative does not have any economic aims, it mostly operates in the social and ecological sustainability dimensions and combines the two by creating a meeting place and location for social learning that focuses on sustainable gardening and facilitating self-supply. Thus, many of the sustainability dimensions are touched by the initiative, implying a certain transformative potential towards a sustainable urban food system.

Conclusion

The results of the case study show that GrüneBeete e.V. does not try to overthrow the current system, but rather to show alternatives to regime structures while simultaneously raising awareness and stimulating behavioural change. It does so by focusing on social aspects such as learning and education, community, and participation. Urban gardening might only be one of many niche innovations and a puzzle piece in inducing a food system transition, but it

offers people a safe space where they can meet like-minded people and where shared values and opinions form that can facilitate an overall system change.
The city of Münster, being the winner of the German Sustainability Award of 2018 and a city with high levels of education, offers very favourable conditions for sustainable innovations. This needs to be taken into consideration when assessing local sustainable grassroots initiatives and the applicability of their structures to other cities. The role of authorities and policy-makers in supporting niche developments therefore deserves more attention. Further research might also be needed to find out to what extent the initiative (and other urban gardening projects) attracts members who already follow sustainable consumption patterns, if these patterns become even more sustainable, and if the initiative can, in reality, contribute to the formation of sustainable consumption patterns in people who have previously followed unsustainable "mainstream" patterns.
Taking into account the impact practices can have on sustainability transitions and assuming that the economic growth paradigm is the root of unsustainable practices, urban gardening – particularly if it continues to spread – can make a considerable contribution by providing regular first-hand experiences and influencing the urban population's values and beliefs. And indeed, the concept of urban gardening is spreading: one main topic in the German Garden at the International Horticultural Exhibition 2019 in Beijing is how urban gardening can contribute to the sustainable development of metropolitan areas.

Abstract

The Nigerian rural economy is driven by 70% of rural subsistent smallholder farmers who produce 90% of Nigeria's food. These proportions of the population are engaged in various agricultural related businesses that sustain their rural households. The persistent decrease in the world crude oil prices has squeezed the Nigerian economy with an estimated population of 182 million people. This situation calls for attention to agriculture to revive the crumbling economy. The agricultural sector in Nigeria contributes 23% of the GDP and employs about 75% of the working population directly or indirectly. Most of these people are engaged in agricultural production, processing, warehousing, marketing and distribution and different agricultural enterprises. Agribusiness therefore becomes a sure way for economic recovery. A robust investment in agribusinesses in Nigeria will enhance job creation, provide income, reduce poverty, improve GDP and improve the livelihood of the rural population. This article made a review of the potentials of agribusinesses in growing Nigeria economy. The research adopted a desktop approach making statistical presentations and analysis of the present agribusiness situations in Nigeria. Documents from the National Bureau of Statistics (NBS) were used as secondary sources of data. The review made policy recommendations based on statistical evidences as reviewed.

Keywords: *Agribusiness, Rural Development, Rural Population Potential, Evidences, Nigeria.*

Introduction

Nigeria with an estimated population of more than 160 million people has the largest population in Africa and accounts for 47 percent of West Africa's total population (World Bank, 2012). According to Ahmed *et al.* (2015), the Nigerian economy is undoubtedly dominated by crude oil sector with regards to revenue generation and foreign exchange, but agriculture holds the key to sustainable development of the country with respect to provision of employment opportunities, the provision of raw materials for agro-industries, a source of income for rural families, and perhaps most importantly, provision of food for the population. The dwindling Nigerian economy could leverage on the potentials of agribusiness enterprises and subsectors to attain growth through sustained employment, income generation, provision of raw materials for infant industries and efficient marketing network. The surging population of youths in Nigeria is a great potential if engaged in the agribusiness. According to Tersoo (2013), the centrality of agribusiness in growing Nigerian economy cannot be overemphasized. According to Ekpo and Umoh (2013), agribusiness contribution to the economy of Nigeria decreased to 14% in 1980-88 and increased to 18.2% in 1991-98. This increase could be attributed to government policy to diversify the Nigerian economy and break the dependence on crude oil production. Despite the huge government financial investment in the production of crude oil and income generated through the export of crude oil, unemployment, hunger and poverty are on the increase. This situation requires a proactive action to improve the agribusiness sector in other to grow the economy. The ongoing Agricultural Transformation Agenda (ATA) of the Federal government could be leveraged upon to develop the agribusiness sector. The study therefore was carried out to examine estimated area of cultivated land for various agribusiness enterprises and production output, ascertain the contribution of agribusiness enterprise to Nigerian GDP and examine income generated from selected agribusiness enterprises in Nigeria.

Material and Methods

The study carried out in Nigeria made use of secondary data obtained from National Bureau of Statistics (NBS) statistical bulletin on agricultural land use, agricultural business enterprises and production output and contribution of agribusiness enterprises to National GDP from 2010 - 2018. The review presented obtained secondary data through the use of descriptive statistical tools such as tables, frequency and graph. The study adopted a desktop research approach in reviewing relevant documents and official data facts in agribusiness potentials in growing the Nigerian economy. Nigeria has an estimated population of 182 million with a population growth rate of 2.7% per annum (NPC, 2006). It has an annual rainfall of 400 to 600 mm. Agriculture is one of the major occupations of the majority of the people. The climate is tropical with distinct rainy season and dry season.

Agribusiness Concept

In Nigeria, agribusiness is the business of agriculture involved in the production, processing, and distribution of food and other agricultural products including the financial and other institutions that fund or assist or contribute to these activities. These activities include farm production, storage, processing, marketing, distribution and transportation of farm commodities and products to the end users (Consumers). The agribusiness concept seek to change the traditional production and sale of the products to identifying business opportunities that exist in the value change of each agricultural enterprise and subsectors that enhance income generation and employment of the individuals in the social system.

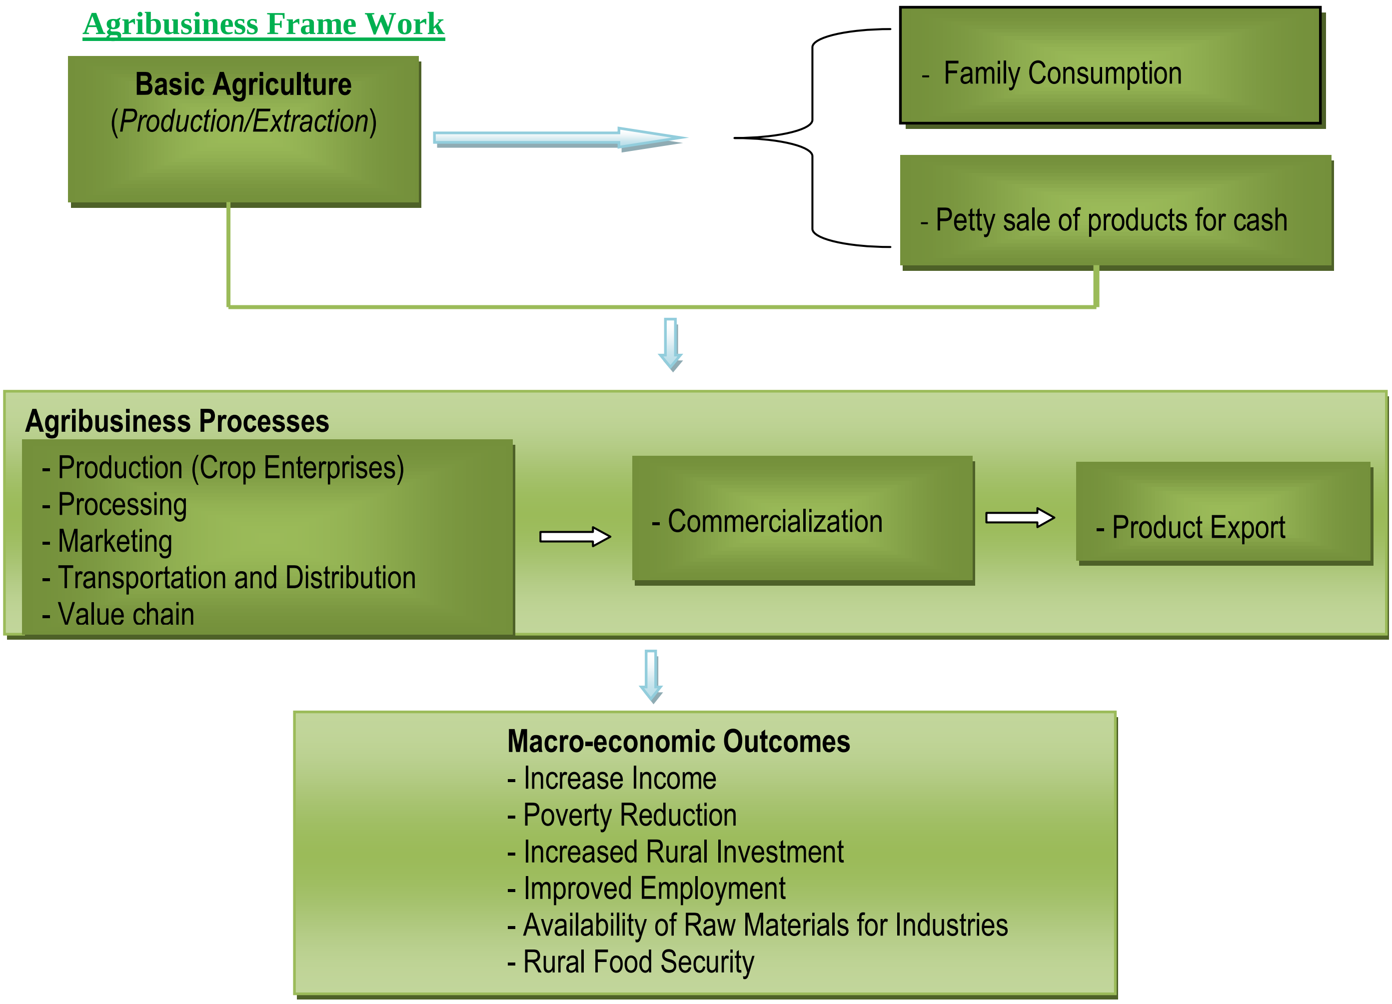
The Concept of Rural Development

Development is a concept that is not limited to certain specific activities but recognizes the existence of change in various aspect of human life. All societies, rural and urban, are changing all the time. These changes affect the society's social norms and values, institutions, methods of production, attitudes of the people and the way in which it distributes its resources. Development refers to some form of action or intervention to influence the entire process of social system. When these interventions or actions happen in the rural area, it is referred to as rural development. It is a dynamic concept which suggests a change in, or a movement away from, a previous situation. In the contest of agribusiness process, agricultural production in the rural society is expected to be infused with business ideas that will change the fortunes of the rural farmers.

Agribusinesses and Rural Development in Nigeria

Agriculture is the basis of the livelihood of most rural families. Agribusiness therefore is expected to engineer the development in the rural society especially in the areas of economic development (production and income generation), social development (provision of social amenities) and human development (capacity building). According to Onwumere and Onwusiribe (2013), agribusiness comprises businesses that either supply farm inputs or are involved in the marketing of farm products through warehousing, processing, wholesaling and retailing. This implies that agribusiness facilitates production and supply to meet the demand in the rural society. The synergy between agribusiness and rural development is captured by Todaro and Smith (2011) in their assertion that rural development, though dependent primarily on small-farmer agricultural progress, implies much more. Rural development through agribusiness process encompasses (a) efforts to raise farm and non-farm rural real incomes through job creation, (b) decrease inequality in the distribution of rural incomes and (d) the capacity of the rural sector to sustain and accelerate the pace of improvements over time.

Agribusiness Frame Work



Adapted from Ikenwa *et.al* (2017) with adjustments

The framework outlined the transition from subsistence agricultural production (family consumption) to agricultural business model including crop production (various crop enterprises and subsectors), processing, marketing, transportation and distribution and value chain. The business model will ensure efficiency in production, labour productivity, maximum input utilization, employment, income generation and food security. According to Tersoo (2013), there is a synergy in the agribusiness – rural development nexus through inputs supplies, processing and distribution.

Results and Discussion

Agricultural production in Nigeria is anchored on the efficient utilization of land. Most often, intercropping is the commonest farm practice to ensure land use efficiency. Agribusinesses in Nigeria depend on production output of the various crop enterprises in relation to hectare of land used.

Table 1: Estimated Area of Cultivated Land for various Agribusiness Enterprises and Production Output

Agribusiness Enterprises	State	Land Area (Ha)	Production Output (Metric tons)
Beniseed	4	5, 900	13, 260
Tea	18	339, 590	176, 870
Cashew	21	163, 590	87, 970
Cassava	36	6, 669, 000	60, 529, 860
Cocoa	7	1, 158, 390	323, 620
Coffee	11	47, 410	31, 490
Cotton	18	406, 160	195, 100
Garlic	13	42, 960	179, 060
Ginger	7	38, 000	174, 630
Groundnut	31	2, 566, 390	3, 487, 330
Gum Arabic	9	17, 070	13, 750
Kolanut	18	213,700	159, 460
Maize	36	5, 905, 910	10, 532, 340
Oil Palm	24	1, 897, 030	1, 519, 220
Rice	36	4, 101, 180	10, 516, 560
Rubber	9	87, 970	66, 800
Yam	27	5, 347, 480	48, 982, 620
National	**36**	**29, 007, 730**	**136, 989, 940**

Source: National Bureau of Statistics (2017)

Available statistics reveals that the agriculture sector has the highest land investment for production. Nigeria is blessed with favourable environment and climate to grow crops, rear animal and fish in all the states of the country and provide food all year round. Table one shows investment in land area and production output for various crops. At the National level, area of land cultivated for various crops is about 29 million hectares with production output of about 136 million metric tons every year. The production of these crops involves various value chain activities that provide employment for rural and urban populace in the country.

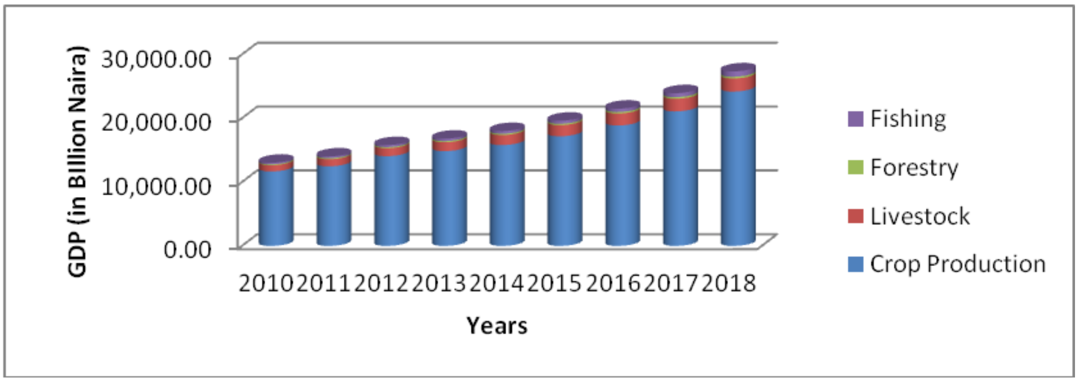


Fig 1: Agribusiness Sector Contribution in (₦'Billion)
Source: Author's Computation with data from National Bureau of Statistics (NBS, 2018)

The contributions of agriculture to the Gross Domestic Product (GDP) of Nigeria cannot be under estimated. Fig.1 reveals that from 2010 to2018, the contribution of selected agriculture sector increases on a yearly basis. In 2018, the sectors contributed about ₦27 Billion Naira to the Nations GDP. This contribution is enormous and marks agriculture business as a veritable option with the potential of growing the Nigerian economy.

Table 2: Estimated Income Generated from Selected Agribusiness Enterprises

Agribusiness Enterprises	**Output(Kg)**	**Average Price (₦)/Kg**	**Total (₦)**	**Average Price ($)/KG**	**Total ($)**
Beniseed	13,260,000	291.76	3,868,737,600	0.810444	10,009,826
Cashew	87,970,000	88.68	7,801,179,600	0.246333	21,669,943
Cassava	60,529,860,000	52.83	3,197,792,503,800	0.14675	8,882,756,995

Source: Author's Computation with data from National Bureau of Statistics (NBS, 2017)

Table 2 indicates the Naira worth of income generated through different agribusiness enterprises in Nigeria. These enterprises generated about ₦10 trillion amounting to $29 billion in 2017. This indicates that with well articulated investment in agribusiness enterprises and other agricultural subsectors, the Nigerian economy will no longer depend on crude oil to grow her GDP and the National income. The income generated with good governance and political will, can finance the National budget and provide infrastructure for development

Agricultural Businesses in Nigeria – The Constraints

The potentials of agribusinesses in growing the Nigerian economy face a lot of challenges and drawbacks. The following are considered as some of the constraints of agribusiness development in Nigeria; land use policy, poor budgetary allocation, inadequate application of modern technologies, poor agricultural infrastructure and inadequate incentive for youths to participate in agriculture.

Conclusion and Recommendation

The potentials of agribusiness in growing the Nigerian economy are enormous if optimally harnessed. Agribusiness impacts on the GDP of the economy positively. Agribusiness investment creates income, generates employment, improve food security status and reduce the level of poverty in the country.

Based on the reviews made and the statistics projected, the following recommendations are made; government should improve budgetary allocation to the federal ministry of Agriculture and Rural Development, the Land Use Act of 1978 that empowered the Governors and Local Government Authority to grant customary rights of occupancy to any person or organization for agricultural, residential and other purposes should be enforced and the agribusiness sector should be mechanized, commercialized and industrialized to enhance its contribution to the economy.

CONSUMER BEHAVIOUR AT THE LOCAL FOOD MARKET

Marta CZEKAJ[1*], Dawid BEDLA[2]

Abstract

Consumer behaviour at the food market is determined by several factors which can be classified as external and internal. Literature review points out that the most important factors are economic components, however economic, social and environmental circumstances cause the emergence of new factors affecting consumers' decisions. The following can be listed among them: consumer ecological awareness, ethical food production, production in line with traditional methods, paying special attention to the quality of food processing, place and manner of food production, place of purchasing food or distribution channels. The paper presents the results of the surveys carried out in 2018 among 371 residents of the Małopolska Province, the aim of which was to determine the attitudes and behaviours of consumers at the food market with special regard to local products. Based on the conducted studies it has been determined that about 1/3 of surveyed respondents prefer buying food on local markets. A third of the contents found in the food products baskets come from local producers. The respondents were also surveyed in terms of reading labels on food products, and it was found that while percentage of such responses is quite high among women (63%), it is very low among men (18%). Four out of five respondents always or sometimes check the price of the products before purchasing them, thus this factor strongly impacts their decisions. The interest of consumers in local food and ability of local producers to meet this demand in the near future will build opportunities to strengthen as well as expand small farms and small food businesses.

Keywords: *consumption, local production, consumer behaviour*.

Introduction

The purchasing behaviour of consumers on the food market has been the source of interest to many scientists (Kwasek, 2015; Szwacka, 2007). These behaviours emerge as part of the elementary cycle of life as they lead to satisfying staple human needs for sustaining life. Typically, the needs are characterised by their renewability, limitlessness, complementarity, substitutability and diversified intensity (Rudnicki, 1996). The complexity of consumer behaviour on the food market results from the diversity of possibilities to satisfy physiological needs, however, the most important action taken on the market of satisfying hunger and thirst is the act of purchase (Sojkin, 2012).

Food consumption impacts our health, as well as affects the ability to live as part of society and the ability to work. The theory of consumption points to consumer behaviour as being divided into a few fundamental areas. The first one is purchasing products, leading to the maximization of marginal utility, i.e. the satisfaction of the user with consumption. A decrease in the price of a product affects the increase in its consumption, an increase in the price causes a drop in consumption. Finally, an increase in real income leads directly to an increase in consumption (Kowalska et al., 2016).

The purchase of a specific good is determined by many factors, which, in the simplest terms, can be divided into internal and external. The latter include geographical, demographic, economic, sociological and situational factors. Internal factors include those of a psychological nature, e.g. age, lifestyle, values, motivations, etc. (Bojkovska et al., 2014). The purchasing process, thus, is impacted by the market situation (price, surplus or shortage of a given good), the economic situation of the purchaser and sociological factors (Szczepański, 1981). Consumer purchasing behaviour on the food market is to a large extent determined by their demographic and economic profile. Different factors will influence the choices of teenagers at the food market, and different will impact the actions of older people (Chrzan, 2018). Family status, household size and the amount of income are only some of the elements that determine the decisions to buy food. The shopping basket of a family with two children will probably differ significantly from the shopping basket of an elderly person, if only because each of these persons has a different demand for nutrients and nutritional substances (Oczachowska, 2010).

Although well known, the food selection criteria are still evolving with changing consumer awareness and views. And although most buyers are guided by the economic criterion while completing the act of purchase (Łuczka-Bakuła, 2011), there are new factors emerging that impact their market behaviour. These include, for example, the environmental awareness of consumers, the production of a given good in line with ethical requirements, certificates proving that a given product is a traditional product (Barska, 2018), or paying particular attention to the extent to which the food has been processed, the place and manner of its production and the place of its purchase as well as the distribution channel through which the food product is being delivered. Consumer ethnocentrism and tendency to buy domestic products (Szromnik et al., 2013), in particular local products, are becoming more and more common among buyers. Manufacturers are also aware of this trend, using names that are closely associated with a particular geographical region or area to designate products. Therefore, it is an excellent tool for promoting local and regional producers (Kowalczyk, 2016). Food manufacturing intended for local markets is usually small-scale, but features a great deal of confidence that consumers have in the manufacturers (farmers and processors). Short supply chains are increasingly being promoted, pointing out that "*local tastes better*" (www.euractiv.pl), thus convincing purchasers to become local patriots.

The main objective of the paper is to present selected aspects of the food purchasing process in the households of the Małopolska Province residents. The study focused on establishing sites the surveyed consumers buy their food products from, the places of origin of the purchased food (from local, domestic or foreign manufacturers), whether the price of food products impacts the respondents' purchasing decisions and whether the respondents are aware of the quality of food they consume and if they read the information on the label of the products they purchase.

Material and methods

The study involved the use of primary and secondary data. Primary data was obtained using a paper questionnaire. The interviewer read the questions and answers and marked the responses selected by the respondents. The method of non-probability sampling has been selected for the study. The survey involved 371 respondents representing households located in the Małopolska province. The study was conducted in 2018. The questionnaire consisted of 31 questions, of which 30 were multiple-choice and one was open-ended. In the preparation of this study only a part of the data obtained during the research process was used. The questions dealt with issues directly related to food consumption, beginning with the place of purchasing food to the amount of food consumed and its form. The source of secondary data is subject matter literature. The obtained results were prepared in a descriptive and tabular form.

The majority of the respondents, 61.2%, were female. The largest number of respondents included people aged 20-31 (29.7%), followed by people aged 32-45 (28.7%) and 46-57

(24.6%). The smallest group of the respondents included people aged 50 and over (17.0%). Approximately 39.0% of the respondents have a university degree, while almost 28.2% of respondents declared completing secondary school education. Among the respondents, 27.9% declared completing basic vocational education. Only 4.9% of all respondents have only completed elementary education. In terms of the number of the household members, the largest group of respondents were people living in five-person or larger families - 24.4% of the sample. About 23.6% of respondents lived in households including three people and 23.3% came from four-person households. Every fifth respondent represented two-person households, while people living alone constituted 9.0% of the total number of respondents. As many as 42.1% of the respondents declared that their families do not have any children at the moment. As regards the monthly income of all household members, the most numerous group of respondents included the wealthiest, with monthly income per household above PLN 6,000 (24.6%). Respondents with a monthly family income up to PLN 3000 constituted 18.7% of the entire surveyed group.

Results and discussion

Table 1 shows consumer preferences (division of the study group with regard to sex) in terms of places for purchasing food products. The first choice of both male and female respondents is a big-box store (supermarket) (approx. 80%), and the second a small shop in the neighbourhood (approx. 40%). The respondents rarely shop on-line. Women are much more prone to do their grocery shopping on the marketplace (38.3% of the women surveyed compared to 25.7% of the men surveyed).

Table 1. Consumer preferences in regard to sites for purchasing food and grocery products*

Specification	FEMALE		MALE		TOTAL	
	%	Number	%	Number	%	Number
Small shop in the neighbourhood	44.9	102	40.3	58	43.4	161
Big-box store (supermarket)	82.4	187	79.9	115	81.4	302
On-line	6.2	14	6.9	10	6.5	24
Marketplace	38.3	87	25.7	37	33.4	124
Other	3.1	7	0.0	0	1.9	7

Source: Own study based on surveys, * answers do not add up to 100, as it was possible to provide more than one answer.

Preferences regarding the place of purchase do not necessarily have to correspond to the actual place of purchase. Thus the questionnaire asked the respondents to determine, in percentage terms, the sources of food consumed in the household, with the total consumption being a 100%. Table 2 presents the results obtained from the study.

The food consumed by the respondents in the most part comes from the big-box store. Approximately 23.4% of the food is purchased at the small neighbourhood shop. Part of the grocery shopping is done at the marketplace (14.5%), another part is home-made or gifts from the family - 5.5% and 4.1% respectively. As far as the source of food consumed in the households surveyed is concerned, there was no definite difference of responses in regard to the sex of the respondents.

Table 2. Source of food consumed in the households of respondents [%]

Specification	FEMALE	MALE	TOTAL
Small shop in the neighbourhood	21.2	26.8	23.4
Big-box store (supermarket)	52.0	53.7	52.7
Market	15.5	12.8	14.5
Gifts from the family	4.9	3.1	4.1
Home-made	6.5	3.6	5.5
Total	100.0	100.0	100.0

Source: own work on the basis of research.

Respondents also defined the extent to which the food they consume comes from local, domestic or foreign producers (Table 3). The studied group purchases around 1/5 of the food that has been imported. It is also great news that the basket of the surveyed consumers includes nearly 80% of domestic (47.4%) and local (32%) manufacturers. The surveyed women are less inclined than men to buy local products over the domestic ones, thus the men have shown a little more local ethnocentrism. It is also great to see less than 1% of products of unknown origin in the shopping baskets of the respondents.

Table 3. The share of local, domestic and foreign food products in the grocery basket of respondents [%]

Specification	FEMALE	MALE	TOTAL
Local manufacturers	30.8	34.0	32.0
Domestic manufacturers	48.2	46.0	47.4
Imported food	20.0	19.7	19.8
I don't know	1.0	0.3	0.8
Total	100.0	100.0	100.0

Source: own work on the basis of research.

Nowadays, the product packaging and information one can find there is the first direct message that may impact the buyer and their decision whether to purchase the product or not (Nieżurawski et al., 2015). The majority of packaging have an integral label which presents the first impression in terms of its quality (Krasnowska et al., 2011). Respondents surveyed in the Małopolska Province were asked whether they read the information on the label when shopping. 50% of the respondents familiarize themselves with the ingredients found on the label (table 4). 18.9% of respondents do it all the time and 31.5% read it sometimes. Among the respondents, only 14.1% of women never read labels before buying a product, while among men this share is much higher and amounts to 42.3%.

Table 4. Selected habits of respondents during purchasing food products.

Specification	FEMALE		MALE		TOTAL	
	%	Number	%	Number	%	Number
Do you read the label on a food product before purchasing it?						
Yes, I always do	23.3	53	11.1	16	18.9	70
Sometimes	40.5	92	17.4	25	31.5	117

No	14.1	32	42.3	61	24.8	92
When shopping do you consider the price of the product you are purchasing?						

Yes, I always do	49.8	113	32.0	46	42.9	159
Sometimes	42.7	97	41.6	60	42.3	157
Rarely	2.6	6	13.2	19	6.7	25
I don't limit my expenses on food	4.9	11	13.2	19	8.1	30

Source: own work based on the study.

Papers analysing consumer purchasing behaviour at the food market point to the significance of the price - the purchase decisions of Polish consumers are impacted by the amount they need to pay for the product (Kowalczuk and Maciąg, 2017; Michałowska 2010). Buyers are willing to spend more money on a food product if the product they purchase is of satisfactory quality for them. Respondents were asked a question: do you take into account the price of the goods you buy? In the study group over 90% of the surveyed women agreed with the statement that they take into account the price of the product they are purchasing, with 49.8% doing it always, and not much less, 42.7%, doing it sometimes. However, the men surveyed much more often than women claimed that they rarely consider the price of the product and that they do not put limits on their expenses on food (Table 4).

Conclusions

In view of the data provided by the literature on the consumer behaviour at the food market in Poland we can see the origins of ethnocentrism are emerging, which can also be seen as a way of supporting rural areas and agriculture. Food purchased directly from food manufacturers enjoys particular consumer confidence. Only small farms can afford to sell on a small scale, directly by the farmer. Selling this way is also an opportunity for the smallest players on the market and gives them a chance to deliver niche products which are often in great demand.

These trends are at least in part confirmed by the completed study. Respondents prefer a big-box store (supermarket) as their shopping destination, but when buying food, about 1/3 of them (more often women than men) prefer to shop at marketplaces. These sites often offer grocery products of local manufacturers (farmers) and processors.

The research implies that almost 1/3 of the food purchased by respondents comes from local producers, and the fact that only about 20% of the respondents put imported products in their shopping basket is good news.

Polish consumers are increasingly gaining awareness, they wish to obtain as much information as possible about the food they buy and consume. They are interested in the information found in the product label, as well as in the price of the good. The study points out that only 14% of female respondents do not read labels before buying a product. The percentage of these responses is, unfortunately, three times higher among the men surveyed. The purchasing decisions of the respondents are strongly impacted by the price of a food product, as four out of five respondents always or sometimes check its amount before buying a food product.

Contemporary consumers more and more often consider the general quality of the food purchased, which is, for instance, identified with the place and manner of its manufacturing as well as the extent to which it is processed. This situation is a great opportunity for local food manufacturers, who can take advantage of the gap that is being created for them and ensure the presence of the well-known, well-established and traditionally prepared regional products on the local market.

ECONOMIC ASPECTS OF HAZELNUT PRODUCTION IN REPUBLIC OF SERBIA

Aleksandar MILJATOVIĆ*, Veljko VUKOJE

Department of Agricultural Economics, Faculty of Agriculture Novi Sad, Serbia
*Corresponding author: aleksandar.miljatovic@polj.uns.ac.rs

Abstract

Areas under hazelnut made 1.8% of total areas under fruits in Republic of Serbia in 2017 and significant increase was recorded in comparison with previous period (7.9% relative to 2016 and 19.1% in comparison with 2015). In this work, costs and achieved results in hazelnut production are analyzed on the agricultural holding from Republic of Serbia which is primarily involved in crop production. The main aim of the research is to determine profitability level in hazelnut production. Average hazelnut production in the world, from 2008 to 2017, was 863,847 tons. Turkey predominates with 66.3% share in world production, then follow Italy with 12.3% and Azerbaijan with 3.8%. Hazelnut production demands high labor share primarily because of the fruit collection and crunch the hazelnut. Because of that, in the cost price structure labor cost are dominant with 37.7%, followed by depreciation of equipment costs with 34.6%. Material costs made 12.1% of total production costs. Coefficient of economy is 2.23 and profitability rate is 55.1%. Investment in raising the plant is payed for 9 years and 259 days, which is relatively long period of time but it is important to emphasize that the period of profitable orchard exploitation can be more than 50 years. Also, investment in modern equipment can additionally intensify hazelnut production which represents good way for increasing earnings of agricultural holdings, with multiple positive effects on increasing export, rural and whole agrarian sector development in Serbia.

Keywords: *Hazelnut, profitability, coefficient of economy, agricultural holding.*

Introduction

The hazelnut is significant fruit species which fruits are extremely appreciated on domestic and foreign market. Hazel bush originated from East Asia, where from it has spread to the west towards Southern Europe and North Africa. It is one of the oldest useful plants known to man since the "Stone Age".

The nut of the hazel have about 60% fats, 14% of proteins and about 7% of carbohydrates. It is an excellent source of vitamin E and vitamin B6 (*Zhao et al., 2017*). Hazelnut can be consumed underdone, roasted and dried and it also can be used as a raw material in confectionery industry. The nut of the hazel can be also used in precise and airplane industry, painting and perfumery. Tannin, obtained from the hazel crust and leaf, is used in medicine. Shell, which is an nus product obtained in hazelnut production, is characterized by high calory value and it is more favorable heating material than other solid fuels.

Average hazelnut production in the world, from 2008 to 2017, was 863,847 tons. Asia is the continent which dominates in the world production with 78.9% share, followed by Europe with 16.2% and North America with 3.9%. Turkey with 66.3% is the country with the highest share in world production, while Italy with 12.3% and Azerbaijan with 3.8% are the second and third world producers of hazelnut (*FAOSTAT, 2019*).

Republic of Serbia (RS) participates with 0.5% in the hazelnut world production and with 3.0% in european production. Areas under hazelnut made 1.8% of total areas under fruits in RS in 2017 and they increased for 7.9% compared to last year, while the increase was even more in comparison to 2015, 19.1% (*RSO, 2019*).

Hazel bush can be grown on different types of land, from neutral to acidic. Irrigation is necessary more times during the vegetation period. It can be grown without regular protection, but when is grown in plantation conditions it is necessary to protect hazelnut from various parasites, harmful insects and diseases. RS has favorable natural conditions for raising hazelnut plantations.

The paper primarily considers economic aspects of hazelnut production on the agricultural holding (AH) from AP Vojvodina[16]. The main aim of the research is to determine and evaluate profitability level in this production.

In the first part of the paper, cost structure and cost price in hazelnut production is considered, while in the second part economic analysis and evaluation of justification of investment in raising hazelnut plantation are performed.

Material and Methods

The material basis of the research are data from AH which is primarily involved in crop production. Also, data from publications of Republical Statistical Office (RSO) and Food and Agriculture Organization of the United Nations (FAOSTAT) were used.

Cost-effective analysis of hazelnut production is based on analytical calculation of primary costs and achieved results in this production (*Lukač Bulatović et al, 2017*). These calculations are the basis for developing an investment plan and deadline of the return of the investment in raising the plant (*Miljatović and Vukoje, 2019*).

Investment in raising the plant was calculated according to the following formula (*Andrić, 1991*):

$$Vm = A + (a_1 + a_2 + ... + a_m)$$

A – investment which was made once during the raising the plant,
a – cost of fertilization, care and protection in some years during its raising,
m – number of years of raising the plant.

Costs in calculation are divided into fixed and variable, whereby the year when was reached full hazelnut yield (the tenth year from raising the plant) was taken as a representative year. Cost price was calculated according to "*the old method*", which means that from total production costs, value of nus product was taken away and the rest of the value presents production costs of main product (hazelnut – the core) (*Vukoje et al., 2015*).

Success indicators, such as profit, coefficent of economy and profitability rate, were calculated. Also, other research methods, such as interview, observation method, "desk research" method etc, were used.

All calculations are based on real market prices of inputs and products from 2018 expressed in euros. Average exchange rate from 2018 was used (€ 1 = RSD 118.27) (*NBS, 2019*).

Results and Discussion

In order to make hazelnut production successful, it is necessary to consider numerous factors which have influence on the economics of production. The economics of production, as production value and production costs ratio, depends on the market price and achieved yield in hazelnut production, from one side, and purchase price (cost price) and quantity of inputs which are spent in the production, from the other side.

In the cost structure of hazelnut production, labor costs are dominant with 37.7% share, because of the collecting hazelnut and its processing (*tab. 1*). If these jobs were completely mechanized, labor costs share in the cost structure would be significantly reduced.

Material costs made 12.1% of total hazelnut production costs. Therefrom, pesticides with 7.0% presents the most important item. Fertilizer and fuel costs have significantly lower share in the total costs (2.7% and 1.7% respectively).

[16] AP Vojvodina (APV) is autonomous province of Serbia, located in the northern part of the country.

B)	TOTAL COSTS (A + 8)				3,008.7
No.	ACHIEVED RESULTS	Production		Price (€/kg)	Amount (€/ha)
		Unit	Total		
9	Hazelnut	kg	1,288.0	5.07	6,534.2
10	Shell	kg	1,512.0	0.08	127.8
11	Subsidies				44.0
C)	VALUE OF PRODUCTION (9 to 11)				6,706.0
D)	PROFIT (C - B)				3,697.3
E)	COST PRICE (€/kg)				2.24

*Source: Author's calculation based on data from agricultural holding

Depreciation of equipment costs have high share (34.6%) in total costs because of the high depreciation base, which is purchase value of equipment used in this production. If household wants to reduce share of these costs, universal mechanization should be used. On that way, depreciation costs would be proportionally distributed on several production lines according to the appropriate allocation key.

Raising an orchard in own direction implies its valuation according to the cost price (costs of its raising). In that case it is necessary to calculate orchard depreciation at a 2% rate if is known that exploitation period is 50 years. Costs of orchard depreciation, calculated on that way, made 5.4% of total hazelnut production costs.

Insurance costs could have significant participation in the cost structure if the crop is provided from harmful events (hail, cold, flood, high temeratures etc). It is necessary to emphasize that the state subsidizes 40%-45% of insurance premium, which affects on the total production costs reduction. On the observed AH insurance costs are 5.6% of total costs (*tab. 1*).

Retail price of hazelnut (core) on the domestic market reches 8.5 €/kg (*STIPS, 2019*). AH sells hazelnut at 5.07 €/kg, and nus product (hazelnut shell) at 0.08 €/kg.

Average yield of hazelnut with shell in the world in a ten-year period (2008-2017) ranged from 1.1 t/ha to 1.8 t/ha. In RS average yield ranged from 1.3 t/ha to 1.5 t/ha (*RSO, 2019*). Hazel bush starts to give some yield in the fourth year. Yield rises from year to year and full

gender hazel bush gives in the tenth year of orchard exploitation period, which is over 50 years (*Novković et al., 2017*).
Subsidies aren’t so significant item in the income structure of hazelnut production. Namely, AH uses the basic incentives in plant production for 33.82 €/ha, and subsidy for diesel fuel for 10.15 €/ha (*Official Gazzete of RS, 2016*).
Coefficient of economy in hazelnut production is 2.23 which means that observed production reaches € 2.23 value of production on € 1 production costs. Profitability rate, as achieved profit and value of production ratio, is 55.1%.
In order to calculate investment in raising the plant all investments which are made once during the raising orchard are taken into consideration (analysis and soil preparation, seedlings, planting, irrigation system, fence). Costs of fertilization, care and protection till year in which revenues are higher than these costs, made investment in raising the plant also (*Andrić, 1991*). In hazelnut production that is the sixth year. Investment in raising the plant, if the investment in equipment is excluded, is about 8,100 €/ha (*tab. 2*).

Table 2. Investment in raising hazelnut plantation (per ha)

No	Investment	Value €/ha
1	Analysis and soil preparation	318.7
2	Seedlings	1,902.4
3	Irrigation system	2,113.8
4	Fence	1,500.0
5	Cost of fertilization, care and protection in the first 5 years	2,273.7
	Total	**8,108.6**

*Source: Author’s calculation

Hazelnut production in not possible without adequate equipment (tractor, rotary mower, atomizer, fertilizer spreader, equipment for collecting and processing hazelnut). If AH sells hazelnut with shell, investment in equipment is lower for hazelnut crunch purchase value. But, in that case, market price will be significantly lower than the price for hazelnut core, ranged from 1.8 €/kg to 2.5 €/kg.
Total investment in raising the plant and required equipment on the observed AH (3 hectares surface area), is about € 49,400. Investment is payed for 9 years and 259 days (*tab. 3*).

Table 3. Return time of investment

Year	Current value of net inflows (€)	The rest of the long-term investment (€)
-		-49,366.9
2019	-1,699.1	-51,066.0
2020	-1,973.9	-53,039.8
2021	-2,248.7	-55,288.5
2022	-1,885.0	-57,173.5
2023	-1,339.5	-58,513.1
2024	781.8	-57,731.3
2025	4,840.9	-52,890.5
2026	8,949.8	-43,940.7
2027	11,525.6	-32,415.0
2028	45,688.2	13,273.1

*Source: Author’s calculation

Relatively long deadline of the return of the investment is the main obstacle to potential producers to invest their money. However, observed in the long run, farms which are primary involved in crop production can resolve that problem by organizing hazelnut production as their second, additional, job. Profit, which they can expect in this production, is 3,697.3 €/ha per year (*tab. 1*). This can be coinsidered as good result, if is known that plum production, which is with the apple most widespread fruit species in APV, gives 1,008.6 €/ha year profit (*Vukoje and Miljatović, 2018*).

Conclusion

Average hazelnut production in the world during the observed period was about 865 thousand tons. Areas under hazelnut in Republic of Serbia are recording increase from year to year. This is explained by favorable natural conditions for hazelnut production, from one side, and quite stable and constant market price, from the other side.

Research has shown that this production, generally observed, can provide satisfactory level of earnings on the investment. Current market price is about 5 €/kg and average yield, which can be expected in full gender year on the observed area, ranged from 3 t/ha to 3.5 t/ha. Cost price of the main product (hazelnut core) is 2.24 €/kg and it is significantly lower than the current market price.

In the production costs structure labor costs predominate with 37.7% share and depreciation of equipment costs with 34.6%. It is possible to reduce these costs with reducing the need for labor force by automation of the production proces and by using universal mechanization, but that requests signifacant investment increase.

The deadline of the return of investment raising the plant is relatively long, 9 years and 259 days. However, long period of orchard exploitation (over 50 years), achieved profit in full gender year (3,697.3 €/ha), high coefficient of economy (2.23) and profitability rate (55.1%) have influence on the positive overall rating of the investment.

Abstract

This paper analyzes the prices of onion. The main goal of this study is to use quantitative analysis to find out the trends in onion price movements and to make a comparative analysis of onion prices in Serbia, Macedonia and Entity of Republic of Srpska (Bosnia and Herzegovina). The onion prices are analyzed for the period 2012-17. The prices in the study are based on the average annual prices. The quantitative analysis was performed by using the method of descriptive statistics and the average annual change rate to determine the trends in changes for the analyzed period. The average annual price of onion in Serbia was 182.40euro/t. The price fluctuated in the interval between 159 and 208euro/t. The price variation in the observed period was low (CV=10.42%). The price of onion in Serbia showed a slightly negative trend, almost stagnation. The annual change rate of onion prices in Serbia in the analyzed period was -0.76%. In Macedonia, the average annual price of onion was 304.07euro/t. The price varied in the interval between 259 and 392euro/ton. The price variation in the observed period was medium (CV=16.90%). The price of onion in Macedonia showed a very slight negative trend, almost stagnation. The annual change rate in the analyzed period was -0.05%. In the entity of the Republic of Srpska, the average annual price of onion was 276.07euro/t. The price ranged between 195 and 364euro/ton in the analyzed period. The price of onion in the Republic of Srpska showed a negative trend. The average annual change rate in the analyzed period was -3.55%. The lowest price of onion was in Serbia. In the Republic of Srpska, the price of onion was 51% higher, while the price in Macedonia was 10% higher than in the Republic of Srpska, and 67% higher than in Serbia. The prices of onion show a negative trend in all analyzed countries (entities).

Keywords: *onion, price, Serbia, North Macedonia, Republic of Srpska*

Introduction

Vegetable production is one of the most intensive branches of plant production, and along with grain production, it is one of the most intensive branches of arable land production. This is confirmed both by the yields produced per unit of area, i.e. the amount of organic matter produced annually per unit of area, and by achieved economic effects. Bearing in mind the importance that this branch of agriculture has in both the production and economic sense for producers as well as for agriculture as a whole, it is justified to expect its further development. The subject of the research in this paper is a comparative analysis of changes in the sale prices of onion in Serbia, the Republic of Northern Macedonia and the Republic of Srpska. The prices were analyzed for a six-year period 2012-2017.

There are numerous examples of applying quantitative methods (statistical methods and methods of operational research) and qualitative methods in analysing, modelling, forecasting and planning of production and economic characteristics of agricultural products and inputs in agriculture.

Mutavdžić et al. 2011 determined the trends in the development of vegetable production and concluded that in the period 2001-2010 vegetable production in Serbia had the following characteristics: the areas under certain vegetables including tomato, pea, cabbage, kale, pepper, carrot and cucumber increased, whereas the areas under potato, onion, melon, watermelon and garlic decreased compared to the previous decade (1991-2000); the average yield of all the analyzed vegetable crops increased (except for beans); the total vegetable production in Serbia rose significantly, primarily as a consequence of production intensification i.e. higher yields. Novković et al. 2014 used the method of descriptive statistics to conduct the analysis of the main production parameters in the production of important vegetable crops for a long-term period in Vojvodina. Lazić 2014 used the descriptive, statistical method to analyze the production and evaluate the development of vegetable production in the countries that are leading vegetable producers in the European Union. The quantitative data on the vegetable production indicated the following 13 countries as the leading vegetable producers in the EU: Spain, France, Germany, the Netherlands, Portugal, Hungary, the United Kingdom, Greece, Italy, Belgium, Poland, Bulgaria and Romania. Based on the defined trends, it was possible to forecast reduction in the areas under vegetables in Poland, Italy, Greece, Bulgaria, Hungary and Belgium, and increase in the Netherlands, Spain and Portugal. The quantitative analysis pointed to the development of cropping practices in vegetable production, since out of the 42 studied cases. Novković et al. 2006 performed a time series analysis of wheat / mineral fertilizers price parities, and used the ARIMA model to forecast the price parity trends in the following period. Mutavdžić et al. 2007 analyzed the tendencies and forecast the movements in price parities of fattening pigs and commercial maize. Mutavdžić et al. 2010 focused on forecasting the price parities of the main field crops based on time series analysis and application of the ARIMA model. Mutavdžić et al. 2017 analyzed quarterly movements of wheat and maize sale prices in Serbia and the Republic of Srpska for the period 2010-15. By applying the method of ratio to the overall quarterly average, the results showed that the prices of grains in the Republic of Srpska are higher. There are also a large number of papers dealing with the prices of vegetable crops through analyses and forecasts of certain vegetable prices. Ivanišević et al. 2015 analyzed the movements of tomato prices in Serbia using the method of descriptive statistics, followed by forecasting its value for the future period based on time series analysis. Novković et al. 2016 performed the analysis and forecast of cabbage prices in Serbia. Novković, Mutavdžić 2016 performed the analysis of bean prices in Serbia by means of descriptive statistics. On the basis of these results, an adequate ARIMA model was applied to forecast the movements of bean prices for the following period.

The aim of the research is to analyze and forecast the trends in onion prices in these countries/entity, as well as to conduct a comparative analysis in order to examine the comparative economic advantages. On the basis of the results of the comparative analysis, it is possible to draw conclusions on the prospects of onion production, as well as the causes of positive or negative trends in the previous period.

Material and Methods

The research methods applied in this paper are quantitative research methods. The quantitative analysis included the absolute prices of onion expressed in euro per ton in Serbia, Northern Macedonia and the Republic of Srpska. The analysis was applied for the period 2012-17.

The average annual prices of onion were first converted into a common indicator, euro per ton, to enable comparison and to reduce the impact of inflation in certain countries. Conversion of the prices into euro was carried out according to the average annual exchange rate of euro based on the data of the National Bank of Serbia and corresponding institutions in the Republic of Northern Macedonia and the Republic of Srpska.

The data were processed using standard statistical instruments of descriptive statistics: arithmetic mean – average value of the studied phenomena ($\overline{X}$) and a rate of change (r). The rate of change was calculated directly from the absolute values of the time series using the following expression:

$$r = (G - 1); \qquad G = \left(\frac{Y_n}{Y_1}\right)^{\frac{1}{n-1}}$$

Where in:
r = rate of annual change; G = constant relative change in a phenomenon; Y_1 = the absolute value of the first member of the time series; Y_n = the absolute value of the last member of the time series; n = the number of the time series members, i.e. the number of years

The analysis was based on the official published data of the Republic Statistical Office of the Republic of Serbia, Republic of Northern Macedonia and Republic of Srpska.
Apart from individual analyses of onion prices, the paper also includes a comparative analysis conducted for these republics. The comparison was carried out using the index method. If in comparing the trends the observed phenomenon did not move in the same direction in different republics, a qualitative comparative analysis was performed instead of calculating the indices.

Results and Discussion

The average annual sale price of onion in the Republic of Serbia in the analyzed period was 182 euro/t. The lowest price was in the last year (2017), when it amounted to 159 euro/t, while the highest price was 208 euro/t in 2013. The price was relatively stable, which is confirmed by the coefficient of variation of 10%. The onion price had a tendency of a slight decrease in the analyzed period, at an average annual rate of -0.76%.
Figure 1 shows the average annual prices of onion in the Republic of Serbia for the period 2012-17.

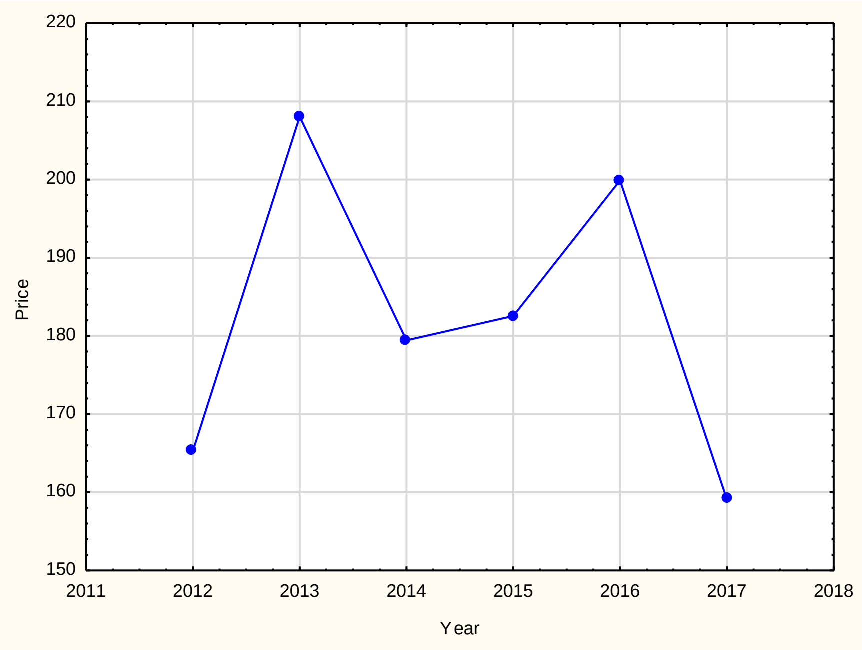

Figure 1: Average annual prices of onion in the Republic of Serbia for the period 2012-17
In the Republic of Northern Macedonia, the average annual sale price of onion in the analyzed period amounted to 304 euro/t. The lowest value of the price of 259 euro/t was in 2017 (as in

Serbia), while the highest value of 392 euro/t was realized in 2013 (also in the same year as in Serbia). The onion price showed moderate oscillations in the analyzed period. The coefficient of variation was 17%. The price had a tendency of a very slight decrease, almost stagnation, since the average annual change rate was -0.05%. Figure 2 presents the average annual prices of onion in the Republic of Northern Macedonia.

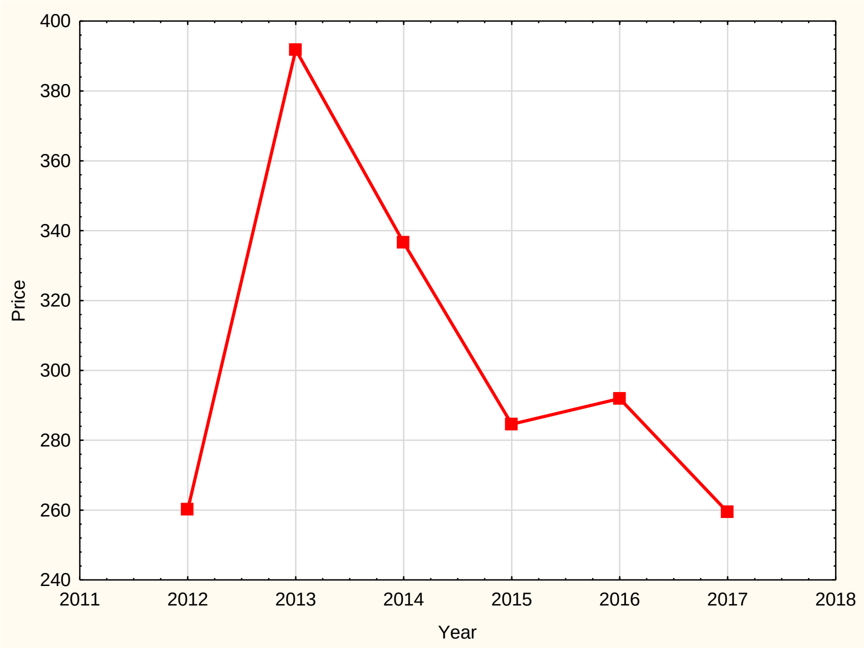

Figure 2: Average annual prices of onion in the Republic of Northern Macedonia for the period 2012-17

The average annual sale price of onion in the Republic of Srpska in the analyzed period was 276 euro/t. The lowest values of the price were recorded in 2016, when it amounted to 159 euro/t, and the highest price of 364 euro/t was in 2013 (in the same year when the highest prices were recorded in the other two observed countries). The price was unstable, which is confirmed by a high coefficient of variation of 21%. The price of onion had a marked declining trend in the analyzed period, at an average annual rate of -3.55%.

Figure 3 shows the average annual prices of onion in the Republic of Srpska for the period 2012-17.

The comparative descriptive analysis of the onion prices has shown the following:

- The Republic of Serbia had the lowest average price of onion. The onion price in the Republic of Srpska was 51% higher than in Serbia, and 10% lower than in the Republic of Northern Macedonia. Northern Macedonia had the highest price of onion, which was 67% higher than in the Republic of Serbia;
- The most stable price was in the Republic of Serbia (the lowest coefficient of variation), followed by the Republic of Northern Macedonia (62% higher than in Serbia), while the most variable price of onion was in the Republic of Srpska, where the coefficient of variation was 105% higher than in Serbia, and 27% higher than in Northern Macedonia.
- The trends of price decrease were recorded in all three observed countries (entities). The most pronounced decreasing trend was in the Republika Srpska. This trend was significantly weaker in the Republic of Serbia, while the price of onion in the Republic of Northern Macedonia practically stagnated.
- It is also important to note that the highest price was reached in the same year (2013) in all three countries.

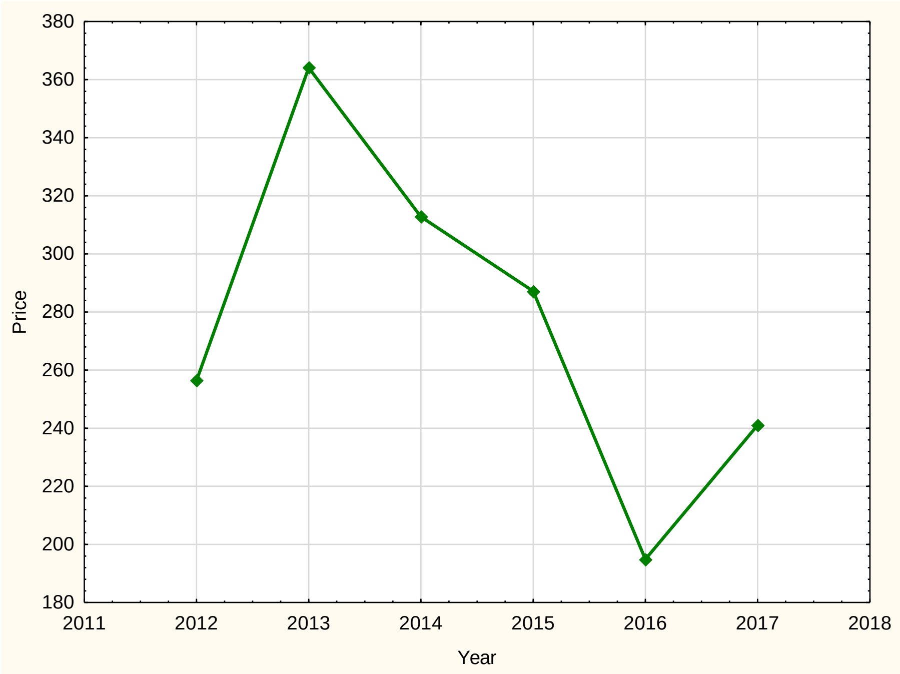

Figure 3: Average annual prices of onion in the Republic of Srpska (2012-17)

Table 1 presents the values of the descriptive statistics for all three analyzed republics. For the purpose of comparison.

Table 1: Descriptive statistics of onion prices in the period 2012-17

Territories	Average	Interval of variation		Coefficient of variation (%)	Change rate (%)
		Lowest	Highest		
Serbia	182.40	159.14	208.06	10.42	-0.76
Northern Macedonia	304.07	259.43	391.81	16.90	-0.05
Republic of Srpska	276.07	194.87	364.10	21.39	-3.55

Conclusion

The results of the study showed that there are significant variations in the prices of onion in different parts of the Western Balkans despite similar natural conditions for production and similar standards of living. It is logical that the price of onion is the lowest in the Republic of Serbia, as it has the lowest standard of living and the lowest level of economic development. However, it is not logical that there are such big differences in prices, which are larger compared to the differences in the standards of living and the levels of economic development.

The Republic of Northern Macedonia had the highest onion prices, which can be accounted for by the existence of a favorable market for vegetables in Kosovo and Metohija. Namely, large quantities of vegetables are placed in the territory of Kosovo and Metohija, which has significant effects on the increase in vegetable prices in general.

The Republic of Srpska has the highest rate of decline in onion prices, so in the future it is expected that these prices will be competitive with the prices in the Republic of Serbia.

Also, it is evident that the mechanism of supply and demand works for the prices of onion. The highest prices were achieved in all three republics in the same year of 2013, which was a very favorable year for onion production.

FARM PRODUCTION EFFICIENCY IN SERBIA

Rade POPOVIC[1*], Zana JURJEVIC[1], Danilo DJOKIC[1], Mirjana BOJCEVSKI[2]

[1]Department of Agricultual economics and agribusiness, The Faculty of Economics Subotica, University of Novi Sad, Serbia
[2]Ministry of Agriculture, Forestry and Water Management, Belgrade, Serbia

Abstract

Process of farm structure changes in Serbia has sped up. Significant decrease of farm number followed by increase of average resources motivates farmers to re-examine their production types. Farm production efficiency becomes more important to understand how they adjust production strategies. The main goal of this paper is to investigate the technical efficiency farms in the regions of Serbia during 2017. All data for 1420 farms used in research originates from Farm Account Data Network (FADN) database. The efficiency analysis is performed on the basis of two criteria: region and production type. In order to determine technical efficiency, input-oriented Data Envelopment Analysis (DEA) with variable return to scale (VRS) was used. The results reveal that farms in region Serbia North are in average more efficient than farms in Serbia South. Also, among production types in plant production higher average efficiency scored farms oriented on horticulture indoor and outdoor, as well as fruit producers. In livestock production types higher average technical efficiency is reached by farms focused on poultry and pig production

Keywords: *Farm, Efficiency, DEA, FADN, Serbia.*

Introduction

Agriculture stands for an important part of the Serbian economy. It create 16% of working places and 6% of GDP (Statistic Office, 2019). Structural changes in agriculture speed up recently. Number of farms decreased for 10.6% in period 2012-2018, and average size of farm, measured in hectares of utilized agricultural land increased to 6.1 hectares, up to 12% (Census of agriculture 2012, Farm structure survey 2018). Family farms dominates in farm structure by 99,7%. Farm structure changes attract attention for technical efficiency research by farm types and by regions.

Material and Methods

Material basis for the paper is Serbian FADN database for 2017. It includes data for 1,420 farms across Republic of Serbia, as representative sample of farm production. Farmers in Republic of Serbia don't have obligation and also practice to keep records of farm business. In past it complicates research of any economic aspects of farm business. Today, well established FADN database enables analysis of production and economic aspects of agriculture on farm level.

Farrell established the modern approach to measuring economic efficiency and its decomposition to technical and allocative efficiency in 1957. Two decades later on the basis of this approach, Charnes et al. (1978) built the first data envelopment analysis (DEA) for estimating the relative efficiency of individual organizations.

In order to assess the technical efficiency of farms, the input-oriented DEA method with variable return to scale (VRS) was used, developed by Banker et al. (1984). According to Coelli et al. (2005) the DEA method variable return to scale (VRS) has advantages over a model with a constant return to scale (CRS) in conditions where imperfect competition exists. This cause a situation in which companies do not operate at the optimum level (size). The advantage of the DEA method in relation to stochastic methods is that it enables the determination of the relative efficiency of each individual unit of observation (Decision Making Unit – DMU) in relation to all other. In this paper DEAP Version 2.1 was used (developed by Tim Coelli). This program is created to construct DEA frontiers for the calculation of technical and cost efficiencies and also for the calculation of Malmquist TFP Indices.

Results and Discussion

The Farrell's study (1957) divided the concept of economic efficiency at technical and allocative efficiency. The focus of this work is on technical efficiency of farms. The analysis of technical efficiency assumes that the evaluated units are doing things right, as determined by the relationship between the consumed inputs and the produces outputs (Kočišová, 2015). There are numerous methods used to calculate efficiency. One such model is nonparametric *Data Envelopment Analysis* (DEA). DEA is a mathematical method based on a linear programming, which is the most often applied to data on a sample of firms (at one point in time) and provide measures of relative efficiency among those firms (Coelli et al., 2005). In relation to the parametric approach for measuring the efficiency (the most commonly used methods in the literature is *the Stochastic Frontier Analysis*-SFA), DEA method does not require a priori specific function of production which is one of the advantages of this model (Madau, 2015; Coelli et al., 2005). Also, the ability to use multiple inputs and multiple outputs in the analysis allows defining best practices for each unit of observation (Mussa et al., 2012). DEA method has been used in many studies and applied in many areas, including in agriculture.

Because this study used FADN databases, experience of researchers from various countries of the European Union, who applied this method to the FADN, are extremely important. It is notable that, depending on the aim of research, this method can be applied to different levels of research. Thus Tóth et al. (2015), Baležentis et al. (2013), Bojnec et al. (2008) have studied the efficiency of farms in Hungary, Lithuania and Slovenia, respectively, in order to define the difference between the individual and corporate farms, differences farming types or production branches. Also, DEA can be applied for comparison between the regions or countries (Table 1).

Kočišová K. (2015) investigated and compared the relative technical efficiency of the agricultural production in the European countries at the national level. The efficiency of the EU agricultural sector has changed over the past few years, and in both models it could be seen that the efficiency has generally decreased over time. Błażejczyk-Majka & Kala (2015) had their own research on the level of the region in the EU, investigating technical efficiency concerning the agricultural production in the USA and the selected regions of the European Union. Fogarasi & Latruffe (2009) investigated the difference in technical efficiency and potential technology gap between French and Hungarian dairy farms during 2001-2006. Results indicate that French farms have a more optimal scale of production than Hungarian farms, but Hungarian farms make better use of the technology.

The use of the FADN database to research the efficiency of different production types is widely accepted in the literature. Tóth & Takács (2015) used FADN data based on legal forms, farm size and type of farming in Hungary. The results have shown that the technical efficiency was the highest in the biggest farms (11–14 SO), in the pig breeding and in the dairy farms. Also, correct the technical efficiency was the highest by the corporate farms and by those farms who deal with animal husbandry. The technical efficiency was very low by arable crops production and by the individual farms. This research points to the importance of small family farms and their role in employment in the agricultural sector in Hungary especially in rural areas. Small family farms usually cultivate only few hectares but their importance in supplementing the family incomes or generating modest surplus is unquestionable**.** Baležentis & Kriščiukaitienė (2013) investigated efficiency across different farming types in Lithuania. The results had shown that mixed crop and mixed livestock (mainly grazing) farming was peculiar with the highest technical efficiency. Bojnec & Latruffe (2008) also used FADN sample for 13 farm business branches in Slovenia in the period 1994-2003. Their results had shown that five farm branches (crop, dairy, livestock using own feed, fruit, and forestry) are fully efficient with respect to all four analyzed efficiency measures (technical, scale, allocative and economic efficiencies), suggesting that these specializations have the best chance to compete on the European and world markets.

Table 1 An overview of studies that use DEA method on FADN database

Authors	*Countries included in the study*	*Level and subject of research*	*Inputs*	*Outputs*
Kočišová K. (2015)	EU-27	*national level:* comparison of EU countries	Total labour input (AWU), total utilized agricultural area (ha), total assets (EURO)	Total output crops and crop production (EURO), total output livestock and livestock products (EURO)
Tóth O., & Takács I. (2015)	Hungary	*farm level:* comparison of individual and corporate farms in the sample from 1,850 farm	Total utilized agricultural area (ha), agricultural employment (AWU), material costs (HUF), depreciation of fixed assets (HUF), livestock (LU)	Gross value of production minus the value of subsidies (HUF)
Fogarasi J., & Latruffe, L. (2009)	France and Hungary	*national level:* comparison of France (6,549 farms) and Hungary (574 farms)	Total utilized agricultural area (ha), total labour input (AWU), capital (EURO), intermediate consumption (EURO), livestock units, milk output per livestock unit, livestock units per agricultural utilized land	Milk output (liters), other outputs (EURO)
Baležentis, T., & Kriščiukaitienė, I. (2013)	Lithuania	*farm level:* comparisons of different farming types	Total labour input (AWU), total utilized agricultural area (ha), total assets (Lt), intermediate consumption (Lt)	Total output (Lt)
Bojnec, Š., & Latruffe, L. (2008)	Slovenia	*farm level:* 130 observations in 13 farm productions branches	Total labour input (AWU), total utilized agricultural area (ha), total assets (SIT), total intermediate consumption (SIT)	Total output crops and crop production, total output livestock and livestock products and other output (SIT)
Błażejczyk-Majka, L., & Kala, R. (2015)	34 regions of the EU in 5 countries	*regional level:* estimates of technical efficiency in regions of EU and USA	Total labour input (AWU), total utilized agricultural area (ha), material costs (EURO)	Total output (EURO)

Farms production in Serbia is very diversified. Only farms with pig and poultry production increased specialisation to some degree, where in several cases farms do not produce feed, using feed industry as only source. In situation where most of farms have multi products it is not easy to find single output. Usually, in such situation money value of all farm products serve as measure of unique output (Table 1). Additionally, in this research value of production is corrected for subsidies and taxes. Main reason for that step is negative balance between subsidies and tax, that occurred in some cases. Value of farm production corrected for subsidies and taxes represent unique result of farm activities in one year, and serve as source for covering all incurred costs of inputs.

Table 1. Descriptive statistics for variables of 1420 DMU, used in DEA method.

Variable	**Unit**	**Average**	**Standard deviation**	**Minimum**	**Maximum**
Value of production + subsidies -taxes	RSD	6.376.101	10.405.680	222.965	152.229.280
Total intermediate consumption	RSD	2.941.988	5.326.118	50.000	115.924.000
Labour input	hour /year	3.896	3.381	170	64.800
Total fixed assets	RSD	19.383.424	46.348.068	647.250	1.508.909.000
Total utilised agricultural area	ha	29	46	0	549

Source: FADN database 2017.

On input side variables for chosen DEA model includes: total intermediate consumption, labour input, total fixed assets and total utilised area. Total intermediate consumption covers total specific crop and livestock costs and overheads arising from production in the accounting year. Labour input is embraced in total number of working hours on farm per year. Total fixed assets includes value of very diversified quantity and quality of fixed resources on farms. Last input variable is total utilised agricultural area, including owned and rented land expressed in hectares.

Table 2. Correlation analysis of input and output variables for 1420 DMU.

	Value of production + subsidies - taxes	Total intermediate consumption	Labour input	Total fixed assets	Total utilised agricultural area
Value of production + subsidies - taxes	1				
Total intermediate consumption	0,817	1			
Labour input	0,410	0,338	1		
Total fixed assets	0,323	0,250	0,124	1	
Total utilised agricultural area	0,651	0,545	0,185	0,351	1

Source: Estimate based on variables from FADN database

Table 2. provide correlation analysis of input and output variables. The strongest positive correlation exist in relation of output variable and total intermediate consumption. This is expectable since first prerequisite for higher farm output is increase of intermediate consumption. Significant correlation is estimated in relation total utilised agricultural area and output variable and between total utilised agricultural area end total intermediate consumption. Labour input and total fixed assets are not correlated with output and other two input variables.

Table 3. Technical efficiency scores by DEA method of farms in North and South Serbia regions for 2017.

	Serbia North				Serbia South

Pigs production	8	0,280	0,497	0,594	24	0,401	0,532	0,735
Total	520	0,252	0,394	0,647	900	0,194	0,333	0,589

Source: Estimate based on DEAP software and FADN database

Estimated technical efficiency for 10 farm types in two Serbian regions, during 2017 showed very diversified results. All farm types in North region, except those specialised in pig production, are more technically efficient than farms in South. The most efficient type of farms in both regions is poultry. In other words, for production one unit of output those farms use the smallest amount of inputs. Among farm types focused on plant production the most technically efficient are those in horticulture business, followed by fruit producing farms. In the group of livestock types of farms the best results showed poultry and pig producing farms. On opposite side, the lowest technical efficiency is scored by dairy farms in South region.

In region Serbia North the most presented type is field crops farms. Farmers in region Serbia South are more oriented on livestock types of farming: mixed crop and livestock, dairying, and livestock production - grazing livestock. In both regions most numerous types of farming scored technical efficiency below level of average efficiency for all farms.

Scale efficiency in all farm types is lower than 1, indicating another way to increase efficiency trough adjusting size of business. In case of 96.9% farms it means increase of resources, while only 1.7% have to decrease its resources on more optimal level. Only 1.4% farms operate on optimum level of resources.

Conclusions

This paper examined technical efficiency of 10 farm types in two regions of Serbia during 2017 accounting year. The results indicated very diversified levels of farm efficiency. It varieties not only among farm types, but through regions. Farms in region Serbia North expectably encountered higher level of efficiency, mainly because better resource structure. The most efficient type of farming were poultry farms, as most specialised one. Extremely dry production season in second half of 2017 significantly lowered results in corn, and soybean production, that complicate production on livestock farms with own production of feed. That can be main source of low technical efficiency of diversified livestock farm types in bouth regions of Serbia.

As improvement, for future research analysis period could be expanding on several years. With inclusion farm data from more years research result can overcome problem with harsh production condition in some years. It is important, since dry or too wet conditions don't decrease output on all farm types in same manner.

Abstract
Both theoretical and practical importance have recently been attached to an analysis of the operating profit margin or earnings before interest, taxes, depreciation and amortization (EBITDA margin) as a measure of the long-term performance of companies. In the integrated financial reporting it is presented through various indicators based on it. In view of this, we have made a comparative analysis of the operating profit margin and its impact on the performance of food trade companies in Serbia and comparable countries. Under the influence of different factors, the dynamics of the size of the operating profit margin of food trading companies in Serbia varies from comparable global food retailers in various countries. The EBITDA margin of the leading food trading companies in Serbia is lower than the in analyzed comparable food retail trade companies. It points to the conclusion that it is necessary to efficiently manage revenues, costs, profit, assets, and financial structure in order to improve the performance of food trading companies in Serbia in the future**.** The general conclusion is that it shows a growth tendency and is, nevertheless, lower in comparison to food trading companies from countries of a developed market economy. In order to increase the operating profit margin, as a measure of long-term performance, it is necessary to manage the financial structure of the food trading companies in Serbia as effectively as possible. (JEL codes: L81, M31, M41, O32)

Keywords: *net profit, interest, tax, depreciation, amortization.*

Introduction
Considerable theoretical and practical attention has been paid in recent years to analyzing the operating profit margin or earnings before interest, taxes, depreciation and amortization (EBITDA margin) as a measure of the long-term performance of companies. On the basis of it, special indicators of long-term performance of companies have been developed. They are comparatively analyzed by individual companies (from the same and different sectors) and based on this –their long-term business success is recognized. Bearing this in mind, the subject of research in this paper is a comparative analysis of the operational profit margin of food retail enterprises in Serbia and comparable foreign retailers. The aim of this research is to thoroughly investigate the problems of the operating profit margin as one of the determinants of the long-term performance of food trading companies in Serbia and, on that basis, to propose the measures for its improvement in the future. This gap is to a certain extent filled with this paper, in what we find its scientific and professional contribution. The basic hypothesis of research in this paper is that the operating profit margin is a significant measure and determinant of the long-term performance of food trading companies. For these reasons it is necessary to investigate it more extensively on the example of food trade companies in Serbia, particularly the dynamics and factors of its size. In this paper, we will explore the dynamics of the size of EBITDA margin of well-known global food retailers, such as Wal-Mart, Tesco and Ahold Delhaize, in order to make comparisons of the EBITDA margin with Serbian trading companies. This provides the basis for proposing adequate measures to increase the size of the EBITDA margin, as a measure of long-term performance of food trading companies in Serbia. The EBITDA margin of the analyzed leading food trading

companies in Serbia (Ahold Delhaize Serbia, Mercator-S and IDEA) is lower than that of analyzed comparable food retail (primarily food) trade companies from the developed market economies. Overall, more efficient management of the financial structure of capital, sales revenues, costs of goods sold (including operating costs, interest) and profit can significantly influence the increase in the EBITDA margin as a measure of the long-term performance of food trading companies in Serbia. This will definitely have a positive impact on the dynamics of the size and efficiency of investments, as a key factor in the performance of food trade companies in Serbia.

Material and methods

For the needs of the research of the treated problems in this paper, empirical data from the Agency for Business Registers of the Republic of Serbia were used. They are completely comparable to the same type of other global food retailers 'data and, in this sense, there are almost no restrictions on the obtained research results in this paper due to the fact that we used empirical data from their publicly disclosed financial statements in this study. With the defined aim and research hypothesis, the basic methodology in this paper is the comparative analysis and application of the relevant statistical analysis. Also, to a certain extent, the historical and normative methodology was applied in researching the treated problem in this paper. The operating profit margin or earnings before interest, taxes, depreciation and amortization (EBITDA margin) as a measure of performance has been used since the mid-1980s, especially since the 1990s in all companies, including wholesale and retail (Levy, 2014). There is extensive literature written on the subject of general problem of measuring the significance of gross operating margin in financial reporting for the needs of more efficient company management (Sui, 2017). However, a number of published papers dedicated to the specificities of gross operating margin analysis in commercial enterprises (food retailers) is significantly lower (Berman, 2013; Corona, 2014; Špička, 2016; Tan, 2016; Calva, 2017; Carstea et al, 2017; Ko et al., 2017; Hoe, 2017; Manini, 2017). This particularly applies to literature in Serbia (Lukic, 2017a, b; Lukic, 2018) – as far as we know, there is no complete work that has been published so far on the issue of the importance of measuring and analyzing gross operational margin in Serbia's trade companies (food retailers). As a measure of long-term performance of (food) retailers, the operating profit margin has its advantages and disadvantages. It is considered that during the usage of this criterion retailers are focused on the performance of fundamental business rather than on financial decision-making related to depreciation of fixed assets, interest and financial structure (lending instead of increasing equity by selling shares) (Levy, 2014). In view of this, it provides bankers, investors, creditors, fiscal authorities and others an insight into the long-term potential options for collecting their retailers' claims. More and more financial analysts are aware of certain problems of interpreting the EBITDA margin, and in order to overcome them, the model of economic additional value (the so-called EVA model) is recommended. Nevertheless, it should also be noted that the very model of economic value addition has its own weaknesses, which primarily relate to subjective assumptions regarding the calculation of capital costs. In conclusion, it is necessary to use both models (EBITDA margin, EVA model) concurrently when assessing the long-term performance of retailers. We are well aware of the fact that in recent years many global retailers, and what we consider quite right, also regularly report on the economic value added (for example, METRO group and others) in the context of integrated financial reporting. In this way, the problem of interpreting the EBITDA margin is partially mitigated. Due to the specifics of the nature itself, way of doing business and the applied financial management strategy, the dynamics of the size of the operating profit margin varies by individual types of trade (wholesale and retail), retail companies and countries in which they operate, retail chains (types of shops) and product categories. This is scientifically proven by the empirical analysis of EBITDA-size dynamics of retailers 'margin which has been carried out from different perspectives. Model of calculating the EBITDA margin, it is determined in the following way: EBITDA = Revenue - Expenses (excluding interest, taxes, depreciation and amortization), i.e. EBITDA = Net profit + Interest + Tax + Depreciation + Amortization. From this last formula it follows that: Net profit = EBITDA - (Interest + Tax + Depreciation + Amortization). For illustration purposes Table 1 shows the model for calculating the EBITDA margin in the global retailer Wal-Mart. Therefore, it is consistent with the model shown above.

Table 1. Model of calculating the EBITDA margin at Wal-Mart (USD $ million)

	January 31, 2018	January 31, 2017
Net income	9,862	13,643
Add: Net income attributable to non-controlling interest Less: Income from discontinued operations, net of income tax Add: Income tax expense	661 - 4,600	650 - 6,204
Earnings before tax (EBT)	15,123	20,497
Add: Interest expense, debt, capital lease and financing obligations	2,330	2,367
Earnings before interest and tax (EBIT)	17,453	22,864
Add: Depreciation and amortization	10,529	10,080
Earnings before interest, tax, depreciation and amortization(EBITDA)	27,982	32,944

Source: https: // www.stock-analysis-on.net, (May 10, 2018)

Results and discussion

The value multiplier is determined as follows:
Enterprise Value / EBITDA = (Market Value of Equity + Value of Debt-Cash) / EBITDA.
It shows how the market values the (retail) firm in accordance with the ability to generate operational profits (Enterprise value/EBITDA (EV/EBITDA). As an illustration, Table 2 shows a value multiplier on the example of a food value chain in the US.

Table 2. Food value chain value multiplier in US, January 5, 2018

	EV/EBITDA
Farm/Agriculture	13.07
Food processing	13.01
Food wholesale	10.43
Retail (grocery and food)	8.40
Restaurant/Dining	12.69

Note: Enterprise Value / EBITDA = (Market Value of Equity + Value of Debt-Cash) / EBITDA.
Source: Enterprise Value Multiples by Sector (US), January 5, 2018, http://pages.stern.nyu.edu/~adamodar/New_Home_Page/datafile/vebitda.html, (May 10, 2018)

The data in a given table show that the value multiplier is different for some members of the food value chain in the US. Thus, for example, it is significantly higher for farming/agriculture (13.07) than for retail (8.40). This is partly due to differences in the very nature of their business. In order to make in-depth analysis of the EBITDA margins in the food retail sector, Table 3 shows a value multiplier of the Wal-Mart retailer and its competitors for 2017 and 2018.

Table 3. Value multiplier,Wal-Mart (January 31, 2017 and 2018)

Wal-Mart Inc., EV / EBITDA calculation	January 31, 2018	January 31, 2017	January 31, 2016	January 31, 2015	January 31, 2014	January 31, 2013
Enterprise value (EV), (USD $ million)	305,207	260,427	260,724	306,165	300,184	297,926
Earnings before interest, tax, depreciation and amortization (EBITDA), (USD $ million)	27,982	32,944	33,640	36,433	35,861	36,489
Ratio EV / EBITDA	10.91	7.91	7.75	8.40	8.37	8.16
Benchmarking EV / EBITDA competition						
Amazon.com Inc.	-	43.74	31.40	33.08	33.45	41.58
Costco Wholesale Corp.	-	12.63	13.27	13.49	12.08	12.30

EV / EBITDA, Sector						
General retailers	-	15.92	12.72	12.34	10.93	10.95
EV / EBITDA, Industry						
Customer service	-	12.26	11.49	10.91	10.77	10.30

Source: https: // www.stock-analysis-on.net, (May 28, 2018)

The data in the given table show that the value multiplier differs between some food retailers. Thus, for example, on January 31, 2018, in Target Corp. it was 6.96 and in Wal-Mart 10.91, respectively. The Wal-Mart value multiplier is lower than the average of the sector and industry. These differences are certainly the result of the implementation of different financial management strategies (lending versus the increase in equity by selling shares). Earnings before interest, taxes, depreciation and amortization differ among individual food retail companies. Table 4 illustrates the dynamics of the EBITDA margin of the global retailer Wal-Mart for the period 2008 - 2017.

Table 4. Dynamics of EBITDA margin of Wal-Mart, 2008 – 2017

End of period	WMT
January 2008	NA
January 2009	7.3%
January 2010	7.6%
January 2011	7.9%
January 2012	7.7%
January 2013	7.7%
January 2014	7.5%
January 2015	7.5%
January 2016	7.0%
October 2016	6.8%
January 2017	6.8%
October 2017	6.6%

Source: https://finbox.io/WMT/explorer/ebitda_margin, (May 10, 2018)

Recently, the EBITDA margin has decreased in Wal-Mart compared to the previous period. Compared to some competitors it is larger and compared to others – smaller (for example, Target Corporation 9.9%) (Table 5). This is, partly, the result of the very nature of the industry operations of its own, sector, company size and business operations model (i.e. the applied financial strategy of the business).

Table 5. EBITDA margin of Wal-Mart and its competitors, 2017

Company	EBITDA margin
Spartan Nash Company (SPTN)	-0.3%
Smart & Final Stores, Inc. (SFS)	3.1%
Kroger Company (The) (KR)	4.5%
CompanhiaBrasileira de Distribuicao (CBD)	6.1%
Casey's General Stores, Inc. (CASY)	6.2%
Best Buy Co., Inc. (BBY)	6.2%
CVS Health Corporation (CVS)	6.6%
Wal-Mart Stores, Inc. (WMT)	6.6%
Target Corporation (TGT)	9.9%
Consumer Staples (SECTOR:STPL)	12.5%
Procter & Gamble Company (The) (PG)	25.6%
#ERROR! (CNCO)	N

Source: https://finbox.io/WMT/explorer/ebitda_margin, (May 11, 2018)

Table 6 shows the dynamics of EBITDA margin of Tesco for the period 2014 - 2018.

Table 6. EBITDA margin of Tesco, 2014 – 2018

Fiscal year March-February. All values are expressed in millions of pounds (GBP)	2018	2017	2016	2015	2014
Sales/Revenue	57,491	55,917	53,933	56,925	63,557
EBITDA	2,957	2,581	2,202	(1,733)	4,757
EBITDA growth	14.57%	17.21%	227.06%	-136.43%	-
EBITDA margin	5.14%	-	-	-	-
EBIT	1,663	1,284	-	-	3,225

Source: https://quotes.wsj.com/UK/XLON/TSCO/financials/annual/income-statement, (May 11, 2018)

The data in the given table show that the share of EBITDA margin in revenues is lower in Tesco (5.14%) than in Wal-Mart (6.6%). This is partly a consequence of a different model of doing financial operations. Table 7 shows the EBITDA margin of Ahold Delhaize, which operates in Serbia as Delhaize Serbia.

Table 7. EBITDA margin of Ahold Delhaize

	12/16A	12/17E	12/18E	12/19E
Revenue (€ million)	63,093	63,943	65,348	66,920
EBITDA (€ million)	4,142	4,267	4,507	4,836
EBIT (€ million)	2,420	2,386	2,638	2,923
EBIT growth (%)	7.9	(1.4)	10.6	10.8
EBITDA margin (%)	6.6	6.7	6.9	7.2
EBIT margin (%)	3.8	3.7	4.0	4.4
EV/EBITDA (x)	6.7	6.4	6.0	5.5
EV/EBIT (x)	11.4	11.4	10.3	9.2

Source:https://research-doc.credit-suisse.com/docView?language=ENG&format=PDF&sourceid=emgpm&document_id=1077229781&serialid=7%2F%2FS9ldDW4ewIdMX6A26zlMtYs6VxLxiTmpgD2zQdGM%3D, (May 22, 2018)

In Ahold Delhaize, the EBITDA margin is higher than at Tesco (5.14%) and is approximately the same as with Wal-Mart (6.6%). In the future, there is an estimated growing trend. The EBITDA margin is certainly different among observed countries in which Ahold Delhaize operates. Ahold Delhaize's operating profit margin, observed by individual countries in which it operates, is significantly higher in the US and the Netherlands than in Belgium and Central and Southeastern Europe (to which the Delhaize Serbia belongs). These differences are the result of different general business conditions and applied (financial) business strategies.

Table 8 shows the EBITDA margin of the Russian company X5 Retail Group for the period 2012-2016.

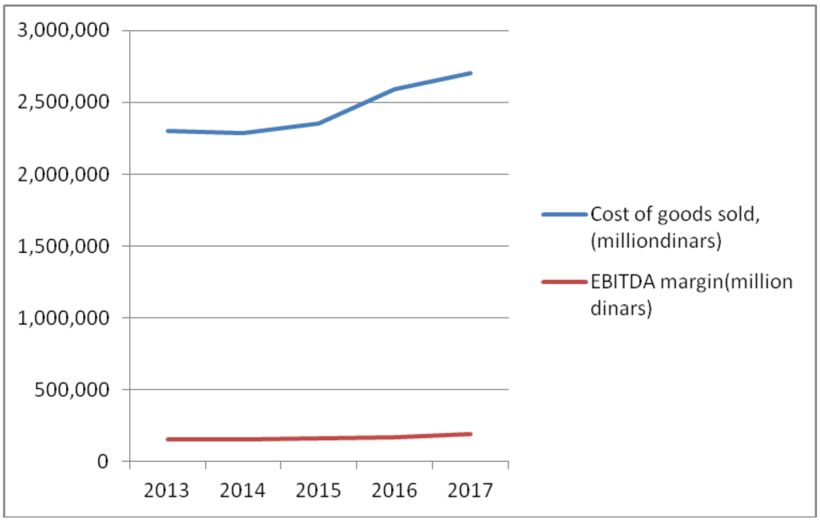
Table 8. Dynamics of EBITDA margin of the company X5 Retail Group, 2012-2016

	EBITDA Margin (Rub bn)	EBITDA margin, %
2012	35,1	7.1%
2013	38,4	7.2%
2014	46,4	7.3%
2015	59,4	7.3%
2016	79,5	7.7%
2016/2015	33.8%	

Source: Q1 2017 Financial Results, X5 Retail Group, Moscow, Russian Federation 27 March 2017, https://www.x5.ru/en/Documents/X5-Q1-2017-Financial-results.pdf, (May 12, 2018

The data in the given table clearly show that the EBITDA margin of the company X5 Retail Group is higher than in Wal-Mart, Tesco and Ahold Delhaize. In other words, its profitability measured by cash flows from operations (using EBITDA margin) is slightly better than the observed retail companies.

In the analyzed period, the costs of goods sold by trade companies in Serbia have slightly increased dynamically until 2015 and from that year up to 2017 much faster, as can be seen from Figure 1. The annual growth rate of the costs of goods sold (3.3%) is thus lower than the annual growth rate of the EBITDA margin (4.99%).To sum up, the return on investments in Serbia's trade companies increased to some extent. In order to make anin-depth analysis of long-term trade performance in Serbia measured by the EBITDA margin, we will show the respective margin for three significant trade companies in Serbia for 2016 (Table 9). Based on the data presented in the given table, we can also conclude that the EBITDA margin of the leading (food) trading companies in Serbia is lower than the analyzed comparable food retail trade companies from the developed market economies.



Source: Business Registers Agency.

Figure 1. Cost dynamics of goods sold and EBITDA margin of trade companies in Serbia

Note: Figure illustrated by the author.

The regression analysis show that the costs of goods sold, as a specific expression of investment, significantly affect the EBITDA margin (Pearson Correlation, 927, Sig. (1-tailed), 012 p <0.05). (The regression equation is: Y = -46285.142 + 0.087 X, where: Y = EBITDA margin, and X = costs of goods sold.) The method of financing working capital (especially inventories) is a significant determinant of the EBITDA margin of trading companies. In this context, we will examine the impact of interest costs on the costs of goods sold of the commercial enterprises in Serbia. The results of the correlation analysis show that there is a negative (statistically significant) strong correlation between the costs of sold goods and interest as a component of the EBITDA margin of trading enterprises in Serbia – this is quite logical – given their character.

Table 9. EBITDA margin of significant trade companies in Serbia, 2016

	EBITDA margin, (million dinars)	EBITDA margin, (% from sales)
Ahold Delhaize Serbia	3,719	4.3%
Mercator-S	3,081	2.9%
IDEA	117	3.99%

Note: Author's calculation.
Source: Business Registers Agency, Belgrade.

Conclusion

Due to the growing EBITDA margin trend and based on the analysis conducted in this paper, we can conclude that the long-term performance of trade companies in Serbia has recently improved. The average operating profit margin (EBITDA) of trading companies in Serbia expressed as percentage of revenue is slightly higher than 5% (Mean 5.1840). However, it is lower compared to the US, Canada, Europe, the Netherlands, Belgium, Central and Southeast Europe, Germany and Russia. More efficient management of the financial structure of capital (financial leverage = assets / capital) can influence the improvement of the return on sales measured by the relationship between the EBITDA margin and total revenues. Costs of goods sold, as a specific expression of the size of investments, significantly affect the EBITDA margin (Pearson Correlation, 927, Sig. (1-tailed), 012 p <0.05). There is negative (but statistically significant) strong correlation between the costs of goods sold and interest as a component of the EBITDA margin, which is quite logical given their character. The EBITDA margin of the analyzed leading trading companies in Serbia (Ahold Delhaize Serbia, Mercator-S and IDEA) is lower than that of analyzed comparable retail (primarily food) trade companies from the developed market economies. Overall, more efficient management of the financial structure of capital, sales revenues, costs of goods sold (including operating costs, interest) and profit can significantly influence the increase in the EBITDA margin as a measure of the long-term performance of trading companies in Serbia. This will definitely have a positive impact on the dynamics of the size and efficiency of investments, as a key factor in the performance of trade companies in Serbia.

CROP PRODUCTION IN THE COUNTRIES OF THE WESTERN BALKANS

Tihomir ZORANOVIĆ*, Vanja ERCEG

University of Novi Sad, Faculty of Agriculture, Novi Sad, Serbia
*Corresponding author: tihomir@polj.uns.ac.rs

Abstract

Crop production is one of the most important branches of agriculture and represents the raw material base for other agricultural production. Areas under basic crops have a dominant share in the structure of sown areas, and the value of realized yields significantly participatesin the GDP of the observed countries. The agrarian budget is an integral part of the total budget of each state and its size speaks about the importance of agriculture in the observed country. The authors analyzed achieved yields for the countries of the Western Balkans, candidates for EU members in all phases. Data for the Republic of Serbia, Bosnia and Herzegovina, North Macedonia and Albania are compared for the production of wheat, maize, rye, barley and sunflower. On the basis of the obtained results, production can be estimated in the next few years for each country in the region. Although, countries with different sizes and different areas for crop production are suitable for comparison of areas and yields over a longer period of time and allows noticeable changes in the structure of production, progress in the yields of individual production, etc. The obtained results enable the assessment of the market supply and self-sufficiency of each country in the near future as well as the potential for export. Adjustment of agrarian policy through the introduction of subsidies and reliefs, as well as the forcing of certain production, allows negative trends to be stopped and the dependence on imports decreases. This is especially important for strategic agricultural products.

Keywords: *Wheat, Maize, Barley, Rye, Sunflower, Western Balkan.*

Introduction

Agricultural land is a non-recoverable resource. In the world, especially in the Western Balkan region, there is a clear trend of decreasing agricultural land in favor of residential and industrial land. If it is kept in mind constantly expanding human populations, then the lack of agricultural area must compensate by higher yields per unit area. Total production must meet the needs of the population, at least. Four countries, which are in various stages of negotiations on EU membership, have been selected for the analysis of production. Production data for individual crop are the basis for negotiating about product quotas for each country and represent a part of the chapter on agriculture in the negotiations. Particularly, it is necessary that individual countries have to negotiate with the positions of net importers of some products because the existing production does not meet the needs of the domestic market.

Material and Methods

The conducted survey is based on the statistical data of each country's production compared to the data collected by different statistical organization such as Statistical bureau of each country, FAO, Eurostat, IndexMundi, Knoema, etc. Data for the Republic of Serbia, Bosnia and Herzegovina, North Macedonia and Albania are compared for the production of wheat, maize, rye, barley and sunflower for last decade, at least. Montenegro was omitted from the survey because the data collected were estimates and production was not significant.

Data are systematized for each country and production separately with the trend of production shown over the next two years.

The charts show data for all years for which data were collected, mainly the period 1990-2019.

Results and Discussion

Serbia, on approximately 500 thousand hectares produces annually around 2.3 million tons of wheat. Production ranged from 1.65 million ton (2010) to 3.4 million ton (2018). There is a noticeable upward trend in production and Serbia is a net exporter of wheat, with an average of over one million tons (Figure 1). Maize production has high oscillations because it is produced mainly under non-irrigation conditions, so in dry years the yield is significantly lower. The smallest production was 3.7 million tons (2012) and the largest 7.7 million tons (2014) with a slight upward trend (Figure 2). Rye production in Serbia has been declining since 2006 and has stabilized at around 10,000 tons on the last 7 years (Figure 3). Barley, with minor fluctuations in production, shows a steady increase with the highest production of 470,000t (2018) (Figure 4). Sunflower, as one of the most important oilseeds, had its smallest production in 2007 (486,000t) and the largest in 2018 (1.1million tons). There is a significant upward trend in production (Figure 5).

Bosnia and Herzegovina, comparing with Serbia, has significantly less arable land under the analyzed crops and it's a net importer of these crops. Nevertheless, it has significant production, on a global scale, of certain crops as rye, where it ranks 12th in the world. Wheat production ranged from 145,000t (2010) to 341,000t (1998). In the last 4 years, it has stabilized at around 300,000t (Figure 6). Maize production is characterized by higher oscillations, from 500,000t to almost 1.2 million tons (2016). For the last 7 years, the average production is just over 800,000t with pronounced annual fluctuations (Figure 7). Rye is symbolically represented in production from 7000t (2010) to 14000t (2019). There is a slight increase in growth but the produced amounts are symbolic (Figure 8). Barley production in the last 15 years has ranged from 48,000t (2014) to 79,000t (2018) with a trend of stagnation at around 65,000t (Figure 9).

North Macedonia has excellent conditions for producing the analyzed crops, but the areas are relatively small. Wheat production is represented in insufficient quantities for the needs of the population, so imports are necessary. Production ranged from 381,000t (1995) with a steady decline to 200,000t (2011). Although annual production fluctuations are around 100,000t, there is a noticeable trend of production decline (Figure 11). Maize production has seen a significant downward trend, especially in the last 7 years, when it dropped from 130,000t (average for 20 years, from 1992 to 2011) to 30000t (2012-2017). The only rise in production was in 2018 (Figure 12). Rye production has stabilized at an average of 9000t over the last 20 years and there is a noticeable trend of production stagnation (Figure 13). Barley production in the observed period was in line with annual fluctuations and ranged from 80,000t to 163,000t. A slight downward trend in production has been observed in the last 27 years (Figure 14). Sunflower quantities ranged from 74000t (1990) to 8000t (2007). If one considers only the last 20 years, a slight upward trend in production can be observed, but at a level below 20000t (Figure 15).

Wheat production in Albania ranged from 615,000t (1992) to 231,000t (2006). In the last 20 years, production have been on an average of about 300,000t with a trend of stagnation

(Figure 16). Maize production ranged from 150,000t (1993) to 381,000t (2017) with a significant upward trend, especially in the last 10 years (Figure 17). Rye production is under-represented and since 2000 has settled at around 3000t (Figure 18). Barley was a significant product until 2000 (42,000 tons in 1990) but declined in 2000 (2000t). After 2000, a slight upward trend can be observed up to 9000t (2016 and 2017) (Figure 19). Sunflower production has been steadily declining, highest production was recorded in 2011 (3045t) and the smallest in 2018(846t) (Figure 20).

http://www.fao.org/faostat/en/#data/QC
https://knoema.com/atlas/Albania/Crop-production-index

Conclusions

Wheat production, as a highly represented cereal in the four analyzed countries, has a trend of production growth, primarily due to the increase in production in Serbia. By world production of wheat in 2019, Serbia take the 24th place with 2.9 million tons, North Macedonia take the 45thplace with 300,000t, Albania is on 46th with 300,000t and Bosnia and Herzegovina takesthe 47thplace with 285,000t.

The amount of maize produced in the analyzed four countries shows that it is the most represented production in Serbia, Bosnia and Herzegovina and Albania. They occupy the following positions worldwide: Serbia 17th place with 6,750,000t, Bosnia and Herzegovina 50th place with 965,000t, Albania 68th place with 375,000t and North Macedonia 82th with 130,000t.

Rye production in Bosnia and Herzegovina is the largest of the fouranalyzed countries and the following countries are ranked globally: Bosnia and Herzegovina 12th place with 14000t, Serbia14th with 10000t, North Macedonia 15thplace with 8000t and Albania 19thplace with 3000t.
Barley is the most represented in Serbia and production is around 440,000t, so Serbia is on the world producer list on 24th place with 440,000t, North Macedonia 39th place with 100,000t, Bosnia and Herzegovina takes 42th place with 75000t and Albania takes 58th place with 7000t. Significant quantities of sunflower are produced in Serbia alone (around 1.1 million tons). From the data collected, it can be concluded that all four countries are trying to satisfy the domestic market with their production. The trend of increasing production is noticeable. Some countries are also significant exporters and are beginning to negotiate production quotas with the EU Commission from better positions. By opening the market and adopting new rules, agricultural production will be under new conditions, which will certainly affect the structure of production as well as the quantity produced.

STRATEGIC APPROACH TO LAND CONSOLIDATION

Milan TRIFKOVIĆ[1], Žarko NESTOROVIĆ[2*]

[1]Faculty of Civil Engineering, Subotica, Serbia

Abstract

Land consolidation is defined and considered as the process through which the fragmented parcels and land ownership are grouped into more functional shapes. Consequently it contributes to reduction of agricultural production costs, increment of agricultural production and consequently increases the competitive potential of agricultural production in certain country. The development of agricultural production is one of more significant aims in contemporary society because of rising demand for food. On the one side the demand for food is expecting to rise, while on the other side the land could be considered as non-renewable and limited resource. What more, the food industry is nowadays treated as commercial issue what additionally increase the complexity of food security problem in the future. Bearing in mind that food is mostly produced by agriculture immediately follows the very big importance of agricultural land. Land consolidation as a process of grouping fragmented land ownership is not only mechanical approach in that direction, actually it allows the improvement of land involved functionality. The functionality of land included in land consolidation process is reflected in increasing efficiency of agricultural production obtained by improvement of road and channel network, regularization of parcels shapes and their grouping. Considered on the level of the country the land consolidation could influence the increase of gross domestic products, food safety and instigate sustainable economic development. In that sense, decision of providing land consolidation on the level of the country is strategic decision which shall be treated as investment in agricultural land preservation and long term development factor. This paper aims to investigate the strategic aspects of the land consolidation.

Keywords: *Land consolidation, strategy, agriculture, economy, sustainable development*

Introduction

Land consolidation is originated by the idea to group fragmented parcels aiming to increase efficiency of agricultural land utilization. Development of basic idea of land consolidation has led to the wide spectra of its utilization and common contributions to the society. The economic, social and environmental analysis of land consolidation showed that all of these parameters were better in the area where land consolidation was provided related to areas where it was not (Crecente *et al.*, 2002). Some negative influence were noticed to the environment because of intensification of mechanization, fertilisers and pesticides utilization but the parcels rationalization is not the main cause of this, but this negative influence is driven by market process. In Japan the effects of land consolidation were researched from aspect of erosion process and the conclusion is that the number of erosion events per hectare in consolidated paddy fields was smaller than in non-consolidated paddy fields (Mihara, 1996). Generally, land consolidation is a tool for ensuring the effective and rational cultivation of farmland and depending on the political, socio-economic and environmental demands to the particular countries or regions places stress on various aspects of it as follows (Sklenička *et al.*, 2009):

- Land reclamation;
- Nature and landscape conservation and
- Social and economic development of countryside.

Interesting approach is to consider land consolidation as the rearrangement of land areas according to developing agricultural technology (Cay & Uyan, 2013). This approach is quite interesting because it suggests that land consolidation should follow the agricultural technology. That means, bearing in mind that agricultural technology is developing permanently, that land consolidation also shall be developed and provided continuously. The measurable effects of land consolidation is increase of arable area from 3% to the 15% obtained by plot amalgamation, the exploitation of unutilized land and reclamation of different kind of devastated lands (Yu *et al*., 2010).
On the level of general aims which shall be obtained by land consolidation it is possible to define them in different ways including increasing competitive approach of countries. In Spain, for example, the goal of land consolidation policies is more connected with productivity than in other European countries' policies (Crecente *et al.*, 2002). The basic objective in Spain is to increase farmers' income by changing the parcel structure and infrastructure and is understood as a sectoral planning tool. In other European countries the policy is connected with spatial physical planning, improvement to landscape and natural conditions. Possibility of land consolidation to response to the wide spectra of general goals supports the idea that land consolidation is a powerful tool for achieving different effects and almost all of them positive. In the developed forms the land consolidation could be utilized for sustainable development of agricultural production.
The arable land is limited and (could be considered) non-renewable resource. According to (FAO, 2010) the global land area is $13.2*10^9$ ha of which the 12% ($1.6*10^9$ ha) is currently in use for cultivation of agricultural crops, 28% is under forest ($3.7*10^9$ ha) and 35% ($4.6*10^9$ ha) comprises grasslands and woodland ecosystems. Low-income countries cover about 22% of land area. The global area of cultivated land has grown by a net $159*10^6$ ha since 1961. This is the difference between area of land newly brought into cultivation, "*while over the same period previously cultivated land have come out of production*" (FAO, 2010). At the same time the irrigated area of land increased more than double and the number of hectares needed to feed one person has reduced from 0.45 to 0.22 ha per person. This reduction is mostly consequence of irrigation system development. Yet, it seems that it is enough arable land for cultivation crops some warning facts and voices are raising. For example: China needs a minimum of $120*10^6$ ha of arable land to feed its people and even though the $135*10^6$ ha is classed as planted with corps it could be not enough to supply the future generations with enough food (Kong, 2014). Sustainable land use is recognized in literature and practice. "*Maintenance of the productive potential of land resources, and checking of land degradation, is fundamental element of sustainable land use*" (Pieri, 1996). Land degradation takes different forms reducing chemical, physical and biological soil properties (Stenberg, B. 1999). Among different forms of land degradation in literature especially are stressed soil erosion (Lal, 1990) and desertification (Puigdefábregas & Mendizabal 1998). Extreme land ownership fragmentation is recognized as a new form of land degradation (Sklenička *et al.*, 2014).
Summarising the significance of arable land (its existential and economic importance for society), its limited amount and increasing need for food and degradation processes which reduce its productive potential immediately follows that every reasonable action shall be provided in order to preserve and develop it. The land consolidation seems to be one of most efficient tools for achieving this goal. Bearing in mind that land consolidation is a tool which provide realization of different sets of goals connected with land resources and cause positive effects on arable land it shall be provided continuously in order to ensure sustainable utilization of land resources.
In this paper the measurable economic effects of land consolidation is considered. Starting from basic principles of strategic approach (forecasting, goals definition and quantification of

return on investment) three different scenarios has been investigated. The scenarios are based on the assumptions that need for food will increase with time and that arable land will be the main resource for food production. The economic aspect is based on the assumption that land consolidation increases the arable area from 3% to 15% (Yu *et al*., 2010). This result is harmonized with the logic that rearrangement of shape and position of parcels could put into function the unreachable parts of them.

Material and Methods

In this paper general economic model is formed to estimate the economic justification of investment in land consolidation. The model is based on the analysis of available statistical data for certain country where the following parameters are included:

- The gross domestic product (GDP) in money units;
- The area of arable land in hectares [ha];
- The costs of land consolidation per hectare in money units;
- The yield of crops per hectare in kg or tones;
- The prices of crops per kg or per ton in money units denoted by $\boldsymbol{p_C}$ and
- Contribution of land consolidation to GDP denoted by $\boldsymbol{d_{KBDP}}$.

The data shall be obtained from official statistics. The economic model was developed in order to obtain results about return on investments in land consolidation (ROI) for making rational economic decisions about land consolidation realization.

Economic model is formed as follows:

$$C_{LCGDP} = AP * C_{LCap} \qquad (1)$$

where:

- C_{LCGDP} – contribution of land consolidation to GDP;
- AP – contribution of agricultural production to GDP and
- C_{LCap} – contribution of land consolidation to agricultural production.

$$\boldsymbol{G_{LCGDP} = C_{LCGDP} * GDP} \qquad (\mathbf{2})$$

where:

- $\boldsymbol{G_{LCGDP}}$ **– contribution of land consolidation to GDP in amount of money;**
- $\boldsymbol{C_{LCGDP}}$ **– relative contribution of land consolidation to GDP and**
- $\boldsymbol{GDP}$ **– Gross Domestic Product.**

$$t = \frac{C_{LC}}{G_{LCGDP}} \qquad (3)$$

where:

- t – period of time in which the investments in land consolidation will return (ROI);
- C_{LC} – land consolidation costs and
- G_{LCGDP} – contribution of land consolidation to GDP in amount of money

$$C_{LC} = A * LC_c \qquad (4)$$

where:

- A – area for land consolidation in hectares and
- LC_c – land consolidation costs per hectare.

The proposed model is based only on the increment of arable land obtained through process of land consolidation and it neglects the other positive effects of land consolidation. This model is chosen in order to test the return on investments based only on this parameter because it was proven in practice while the other parameters (societal, environmental and land protection) are not easy for measurements. Also the assumption is that, under the same conditions, the increase of arable land cause increase of agricultural production. In the case that this model shows the acceptable return on investments then it is possible to make strategic decision to initiate land consolidation process. This decision for land consolidation for one country has strategic characteristic because it engages the significant and rare resources (knowledge, know-how, finance) in order to be successful. Also, those resources are engaged in period of time needed for land consolidation project realization.

Results and Discussion

For case study the data for the Republic of Serbia are taken. According to Statistic Office of the Republic of Serbia the plant production participate in GDP by approximately 5% and there exists $3.3*10^6$ hectares of arable land. According to World Bank the GDP in Serbia was $50.5*10^9$\$ in the year 2018. The contribution of land consolidation according to (Yu et al., 2010) is in increase of arable land between 3% and 15% which corresponds with results from practice in Serbia. This parameter is used to measure the contribution of land consolidation to the agricultural production in three scenarios. The pessimistic scenario is taken as a smallest increase of arable land in amount of 3%; the average (realistic scenario is taken as an average increase of arable land in amount of 9% and the optimistic scenario is taken as maximal increase of arable land in amount of 15%. The cost of land consolidation per hectare (according authors insight in the prices) in Serbia amounts about 200$.The obtained results are given in table 1.

Table 1. Period of ROI for land consolidation (Case study the Republic of Serbia)

Scenario	Pessimistic 3%	Average 9%	Optimistic 15%
C_{LCGDP} [%]	0.15	0.45	0.75
G_{LCGDP} [$]	7.58E+07	2.27E+08	3.79E+08
LC_c [$]	6.60E+08	6.60E+08	6.60E+08
t of ROI [year]	8.7	2.9	1.7

The obtained results showed that even in case of pessimistic scenario the ROI in land consolidation exists and the period of time is approximately 9 years. The other scenarios are proportionately better reaching ROI in approximately 3 years for realistic (average) and approximately 2 years for optimistic scenario. The short period of ROI seem to be the consequence of very low prices of land consolidation in the Republic of Serbia. This could be treated as good chance for providing land consolidation in this period because the prices could rise in the future. In this paper the maximal prices were utilized because in practice the prices could be even smaller.

This model shows that additional benefits obtained by land consolidation only could improve sustainability of land use for agricultural production. Additional benefits of land consolidation as improved road and channel networks shall result with improved efficiency of land use and consequently reduction of area of arable land needed for feed one person per year. For countries which have more arable land than necessary for providing food security it could be the chance to export surplus of agricultural production.

Conclusions

The arable land is and it will be in the future the main source of food for humanity. Its limitation and non-renewability in the conditions of intensive use and many processes of degradation force the research for its protection and preservation. Existing knowledge points the land consolidation as a most efficient tool for achieving that primary goals connected with arable land.

Secondary goals of land use are the economic effects of agricultural production. The countries with agricultural land have two choices depending on the amounts of their agricultural land. If they possess enough agricultural to only provide food security (or if they lack with agricultural land) for own population should preserve its land resources and increase the efficiency of its use. If they possess more agricultural land than needed for providing food security for own population also shall preserve it but they have a strategic chance to increase their export of agricultural products.

The economic aspects of land consolidation predominantly are in the domain of efficiency (reducing costs and increasing productivity) of agricultural production. Costs reduction are obtained by optimization of parcels size and shape, optimized road networks which reduces costs of mechanization utilization, while the increase of agricultural production is consequence of optimized irrigation systems.

Societal and environmental benefits are difficult for measurements but some research showed that those parameters are better in the regions where the land consolidation was provided related to regions where it was not.

Case study for the Republic of Serbia, provided by model established in this paper, showed that the return on investment is very short even in the pessimistic scenario of arable land increment obtained by land consolidation. In the realistic (average) and optimistic scenarios the return on investment is very short. This is the consequence of relatively low prices of land consolidation per hectare.

Summarizing the justification decision of land consolidation realization, it is possible to conclude that its realization is justified for every country because it is existential resource and also chance for economic development, which also could be paid off only thorough increase the area of arable land.

AGRICULTURAL TRAINING CHALLENGES FACED BY SMALLHOLDER FARMERS IN THE AMATHOLE DISTRICT, EASTERN CAPE IN SOUTH AFRICA

Phokele MAPONYA*, Sonja Louise VENTER, Christiaan Philippus DU PLOOY, Michael Wolday BAIRU, Erika VAN DEN HEEVER

Agricultural Research Council-Vegetable and Ornamental Plant, Pretoria, South Africa
*Corresponding author: maponyap@arc.agric.za

Abstract

Agricultural training plays a strategic role in improving the competitiveness and the productivity of the agricultural sector. This study aimed at identifying the agricultural training challenges faced by smallholder farmers in the Amathole District. Representative sample consisting of 37 smallholder farmers with 801 beneficiaries was taken. A number of smallholder farmers in seven local municipalities were visited: Nxuba (8.1%), Ngqushwa (5.4%), Amahlathi (5.4%), Mnquma (21.6%), Mbashe (54.1%), Buffalo City (2.7%) and Great Kei (2.7%). Quantitative and qualitative design was used with a detailed questionnaire written in English. Stakeholder's discussion and field observations were also part of the data collected. A purposive sampling technique was used to select thirty-seven smallholder farmers. Data was coded, captured and analyzed with the software Statistical Packaged for Social Sciences (SPSS version 24). Descriptive and Univariate analysis were conducted. Results identified the following agricultural training challenges: Soil Preparation, Seed Sowing, Pests and Diseases, Marketing, Harvesting, Transplanting and Post-Harvest Storage. The Univariate analysis showed a high level of positive association among Pest and Diseases (Dependent variable) and the following Independent variables: Water source, Crops planted, Land size, Education and Farming experience. The model fit was predicted by the r^2 at 0.937 (94%) and in general, the higher the r^2, the better the model fits the data and the better interaction between dependent and independent variables. It is thus concluded and recommended that the transfer of agricultural knowledge to support smallholder farmers should be a priority for the government especially the seven training challenges identified by smallholder farmers.

Keywords: *Smallholder Farmers, Agricultural Training, Amathole District, Limpopo Province, South Africa.*

Introduction

Training and education plays an important role in smallholder farmer development and research showed that smallholder farmers can benefit from training in agricultural techniques, business management and marketing skills (World Bank 2013; Danida 2004; Maponya *et al.*, 2015). Failure to address some of these training needs has led to constrained agricultural growth in some districts in South Africa (Maponya *et al.*, 2014; Maponya *et al.*, 2015). It must also be noted and acknowledged that only training that accurately addresses the current needs of smallholder farmers and takes into account their different production activities and challenges offers serious prospects for raising productivity, knowledge, skills and improving their livelihoods. According to Maponya *et al.* (2014), designing this kind of trainings is a complex challenge, and it requires detailed local knowledge and a proper understanding of the challenges faced by smallholder farmers. This will go a long way in designing programmes that effectively target smallholder farmers' training needs.

Amathole district is the second largest economy in the Eastern Cape Province, providing 27% of value added (ECDC, 2014). Agriculture provides only 8% of formal employment but varies greatly within local municipalities. Agriculture in the ex-homelands is mostly small-scale crop farming and open grazed livestock. Farming is for subsistence rather than commercial sale, although some black commercial farmers are present (ECDC, 2014). The coastal belt south of East London is the center of the pineapple farming industry, with citrus, horticulture and livestock also farmed. Significant forestry plantations are sited in both the Amatola Mountains and around Butterworth. According to ECDC (2014), the areas around Peddie and beyond Alice are excellent cattle farming areas. The agriculture sector is expected to grow fastest at an average of 3.36% annually from R 393 million in Amathole District Municipality to R 463 million in 2021 (ECDC, 2014).

The Agricultural Research Council (ARC) was involved in an agricultural project in the Amathole district in Eastern Province, where smallholder farmers were identified, assessed and trained in vegetable production. Research was conducted with the overall aim of training smallholder farmers in agricultural production and business management skills. The objectives were: (1) to describe the socio-economic characteristics of selected agricultural farmers in the Amathole District, (2) to identify and determine training needs faced by smallholder farmers in the Amathole District.

Materials and Methods

The research used quantitative and qualitative methods as a detailed questionnaire written in English was developed for the data collection. The questionnaire used both open and closed ended questions. Data collection included stakeholder discussions and field observations. As part of standard protocol for conducting the study, meetings were held with all stakeholders in the Amathole district namely: (1) Local municipalities, (2) Department of Agriculture, Forestry and Fisheries (DAFF), (3) Department of Rural Development and Land Reform (DRDLR), (4) Local economic agencies, and (5) Local farmers. The aim of the meetings was to introduce and explain the intended project. A purposive sampling technique was used to select 37 agricultural farms. The sampling was used to assess uniformity and homogenous characteristics like infrastructure needs, skills availability, production challenges, agricultural training needs, and water source needs, educational level, land acquisition, size of land, farming experience, source of water, inputs and implements used. Agricultural farms visited in the Amathole district were prioritized based on the agriculture potential of the area namely project type, numbers of projects around an area, size of the land, chances of extending production, water availability, commitment of members to their projects, internal conflicts, working material and infrastructure. As shown in Figure 1, Amathole District had seven local municipalities. Data was coded, captured and analyzed with the software Statistical Packaged for Social Sciences (SPSS version 24). Descriptive and Univariate analysis were conducted.

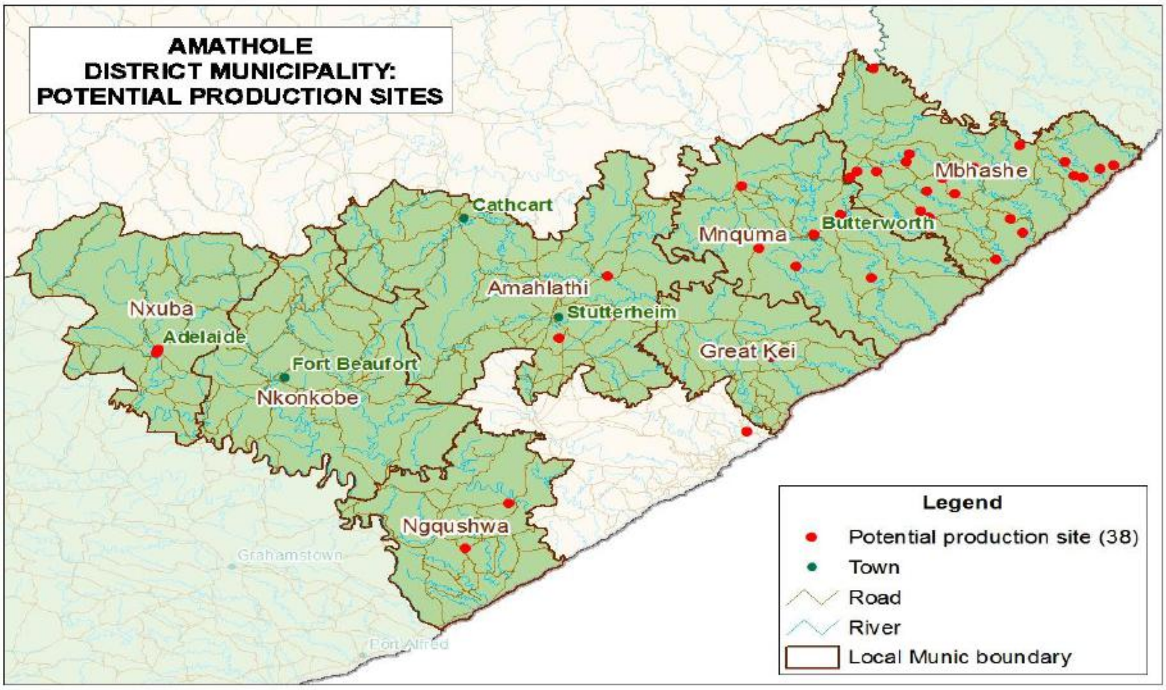

Figure 1. Amathole District with seven local municipalities.

The following econometric model was used to determine association of variables (Greene, 1993):

Wi = _ + _Xi + _i (1)

Where: Wi is the dependent variable value for person i, Xi is the independent variable value for person i,_ and _ are parameter values, _i is the random error term. The parameter _ is called the intercept or the value of W when X = 0. The parameter _ is called the slope or the change in W when X increases by one.

The sample data variables predicted 94% for McFadden (measure for multinomial and ordered logit) variation in the dependent variable was explained by the independent variables. Prediction accuracy were assessed based on the coefficient of determination (R-squared). The coefficient of determination R-squared was used to explain the total proportion of variance in the dependent variable explained by the independent variable. The R-squared removes the influence of the independent variable not accounted for in the constructs. R-squared is always between 0 and 100%. In general, the higher the R-squared, the better the model fits the data.

Results and Discussion

A total of 37 farms in seven local municipalities were visited and spread as follows: Nxuba (8.1%), Ngqushwa (5.4%), Amahlathi (5.4%), Mnquma (21.6%), Mbashe (54.1%), Buffalo city (2.7%) and Great Kei (2.7%). The farms visited had a total of 801 beneficiaries and spread across local municipalities: Nxuba (30), Ngqushwa (30), Amahlathi (20), Mnquma (29), Mbashe (676), Buffalo city (6) and Great Kei (9).

The majority of farmers interviewed were female. According to Table 1, twenty women were interviewed as compared to seventeen females. In terms of educational attainment (Table 1), 5.4% had incomplete primary education, 21.6% had completed primary education, 32.4% had incomplete secondary education, 27% of farm respondents had completed secondary education, 2.7% had incomplete tertiary education and 10.8% had completed tertiary education. These results indicated that educational level of the selected farmers is generally adequate to enable interpretation and understanding of basic farming activities. According to (Maponya *et al.*, 2016) training and education plays an important role in smallholder farmer development and failure to address some of the training needs has led to constrained agricultural growth in some districts in South Africa (Maponya *et al.*, 2014; Maponya *et al.*, 2015). As indicated in Table 1, only twenty-two farmers received agricultural training and whereas fifteen of farmers did not receive any training. The majority of farmers (25) were farming fulltime while only twelve were farming fulltime and working part time. Results on land acquisition (Table 1) indicated that the majority of farmers got land through inheritance (19) while others received land through the following: leased (10), own finance (6) and Land Redistribution for Agricultural Development (LRAD) (2). The age distribution of farm respondents indicated that the majority were in the age group of >51 (35.1 %). As indicated in Table 1, youth involvement is very low (10.8 %), 36 – 45 (21.6%) while 46 – 50 had 32.4%.

The results from Table 2 should be interpreted as follows: 1st – 3rd training challenges = Most challenging; 4th – 5th training challenges = Moderate challenging, and 6th – 7th training challenges = Least challenges. The results showed that 45.9 percent of farmers recognised soil preparation as a 1st training challenge and 2.7 percent of farmers recognised soil preparation as a 2nd training challenge. Table 2 also indicated that 16.2 percent, 5.4 percent and 8.1 percent of farmers indicated soil preparation as a 3rd, 4th and 5th training challenge respectively. Only 2.7 percent and 18.9 percent of farmers recognised soil preparation as a 6th and 7th training challenge. It is very clear that attention should be given to soil preparation as indicated by the 1st, 2nd and 3rd training challenges.
The results indicated that 27 percent of farmers recognised seed sowing as a 1st training challenge and 13.5 percent of farms recognised seed sowing as a 2nd training challenge. Table 4 showed that 5.4 percent, 21.6 percent and 2.7 percent of farmers accepted seed sowing as 4th, 5th and 6th training challenge respectively. Only 24.3 percent of farmers recognised seed sowing as a 7th training challenge. It is very clear that attention should be given to seed sowing as indicated by the 1st, 2nd and 3rd training challenges. The results showed that 21.6 percent of farmers recognised transplanting as a 1st training challenge, 8.1 percent of farmers recognised transplanting as a 2nd training challenge and 5.4 percent of farmers recognised transplanting as a 3rd training challenge. Table 5 showed that 13.5 percent, 21.6 percent and 20.7 percent of farmers indicated transplanting as a 4th, 5th and 6th training challenge respectively. Only 20.7 percent of farmers recognised transplanting as a 7th training challenge
The results showed that 51.4 percent of farmers recognised pest and diseases as a 1st training challenge and 21.6 percent of farmers recognised pest and diseases as a 2nd training challenge. Table 6 showed that 18.9 percent, 8.1 percent and 8.1 percent of farmers indicated pest and diseases as the 4th, 5th and 6th training challenge respectively. Only 18.9 percent of farmers recognised pests and diseases as a 7th training challenge. Almost 76 percent of farmers emphasised pests and diseases as the most important training challenge as indicated by 1st, 2nd, 3rd training challenges. This is a worrying situation and a clear indication that the management of pests, diseases and weeds is still very challenging to many smallholder farmers in Amathole District. The results showed that 10.8 percent of farmers recognised harvesting as a 1st training challenge, 5.4 percent of farmers recognised harvesting as a 2nd training challenge and 16.2 percent of farmers recognised harvesting as a 3rd training challenge. Table 2 showed that 32.4 percent and 8.1 percent of farmers indicated harvesting as the 5th and 6th training challenge respectively. Only 27 percent of farmers recognised harvesting as a 7th training challenge. The results seem to indicate that smallholder farmers are comfortable with harvesting.
The results indicated that 35.1 percent of farmers recognised post – harvest handling as a 1st training challenge, 8.1 percent of farmers recognised post – harvest handling as a 2nd training challenge and 2.7 percent of farmers recognised post-harvest handling as a 3rd training challenge. Table 2 showed that 18.9 percent and 8.1 percent of farmers indicated post-harvest handling as the 5th and 6th training challenge respectively. Only 18.9 percent of farmers recognised post-harvest handling as a 7th training challenge. Post-harvest handling and storage is one of the key constraints faced by majority of the smallholder farmers across South Africa

(Maponya and Mpandeli, 2015) and is thus critical that smallholder farmers in Amathole District should be bettered with postharvest handling skills and knowledge.
The results showed that 56.8 percent of farmers recognised marketing as a 1^{st} training challenge, 10.8 percent of farmers recognised marketing as a 2^{nd} training challenge and 5.4 percent of farmers recognised marketing as a 3^{rd} training challenge. Table 2 showed that 2.7 percent, 13.5 percent and 2.7 percent of farmers indicated marketing as the 4^{th}, 5^{th} and 6^{th} training challenge respectively. Only 8.1 percent of farmers recognised marketing as a 7^{th} training challenge. It is very clear that attention should be given to marketing, indicated as the 1^{st}, 2^{nd} and 3^{rd} training challenges.

Lack of knowledge and agricultural inputs are the major casual factors of training challenges as indicated in Table 3. Results showed that 64.9 percent of farms had no knowledge and inputs to participate in sustainable agricultural production. The same trend was observed in the Mopani District in Limpopo Province, whereby majority of smallholder farmers indicated a lack of knowledge and inputs as casual factors of training challenge (Maponya *et al.*, 2016).

Table 3. Casual factors of smallholder farmers training challenges in Amathole District.

Casual Factors	Number of Farmers	Percentages
Lack of Knowledge	5	13.5
Lack of Inputs	1	2.7
Lack of Knowledge, Inputs	24	64.9
Lack of Knowledge, Inputs, Workers	5	13.5
Lack of Knowledge, Group Conflicts	2	5.4
Total	**37**	**100**

As indicated in Table 4, the odds of farmer's land size, water source, crops planted, education and farming experience were more than 1. This clearly indicated a positive association with pest and diseases as a training challenge. It was not surprising to realise a positive association among water source, crops planted and land size as pest and diseases are mostly transmitted from water sources especially polluted water. Moreover, this pests and diseases challenge can affect any crops planted in any land size. This required an educated and more experienced smallholder farmer to deal decisively with pests and diseases on their farms. According to ARC (2014), many smallholder farmers lack knowledge on the cycles of specific pests, diseases and weeds and find it difficult to distinguish their specific characteristics. As a result, they cannot apply suitable preventive measures nor implement proper control measures. To avoid major crop losses, smallholder farmers must be well trained and monitored to implement affordable and effective measures against pests and diseases (Maponya et al., 2016).

Conclusion

The study identified seven training challenges faced by smallholder farmers in Amathole District, namely: Soil preparation, Seed sowing, Harvesting, Transplanting, Pests and Diseases, Post-harvest handling and Marketing. Based on the identified training challenges, it can be concluded that smallholder farmer experienced a lack of training in Amathole District. It is thus concluded and recommended that the transfer of agricultural knowledge to support smallholder farmers should be a priority for the government especially the seven training challenges identified by smallholder farmers. Smallholder farmers should therefore, be trained in line with the seven training challenges identified by the study. To accomplish these, smallholder farmers should have access to research and training institutions, for example, the Agricultural Research Council, to improve their skills and knowledge. This in turn will lead to higher yields, increased income, increased knowledge and skills, food security and resilience to a changing climate.

SOCIAL INNOVATIONS IN MOUNTAIN REGIONS

Manfred PERLIK*

Centre for Development and Environment, University of Bern, Bern, Switzerland
*Corresponding author: manfred.perlik@cde.unibe.ch

Abstract

Two case studies developed in the framework of the Horizon 2020 project *Social Innovation in Marginalised Rural Areas (SIMRA)* are presented: (a) The Val Lumnezia, a lateral valley in Grisons in the Alps. This Romansh-speaking valley was particularly isolated and characterised by ongoing emigration. An initiative of young craftsmen/entrepreneurs in the 1980s led to a structural change from purely agricultural production to agro-tourist specialisation. They were not guided by a strategy of mass tourism, but were among the first to work together with environmental organisations for environmentally compatible tourism. (b) Val de Travers, a lateral valley in the canton of Neuchâtel in the Swiss Jura, specialised in the watch and micro-industry. The crisis in the watchmaking industry and an increasingly visible division between mountain areas and the littoral plain led to the initiative to develop a mobility and agglomeration concept for the entire canton. They involve both municipalities and local companies in a participatory manner and follow an integrated approach of the local economy (agro-tourism, manufacturing). Social innovation is always triggered by a crisis in the regional trajectory. Such upheavals are often associated with the generational change of the most-important decision-makers. Although civil society initiatives play an important role, public and private institutions must not be neglected and it is the interaction between all three groups of actors that decides on the trajectory of a social innovation.

Keywords: *Mountain regions, Social innovation, spatial disparities, spatial justice, cohesive societies.*

Introduction

Social Innovation has become an important topic also for mountain regions. In the context of global metropolisation, mountain regions undergo a profound transformation where settlements at low and very high altitudes have good chances in the valorization of their landscapes while the intermediate areas risk decline (Perlik, 2019). *Social innovation* has become a popular term but various research communities use the notion in a different manner. Broadly speaking, two different schools can be distinguished in the international debate on social innovations (SI): an Anglo-Saxon school and a continental or Francophone school. The first emphasizes an entrepreneurial understanding, which is ultimately an economic innovation linked to a field of social issues (example: the activities of Muhammad Yunus and the Grameen Bank in Bangladesh), while the continental/French-speaking understanding follows an institutional approach (e.g. Andrew and Klein, 2010; Fourny, 2018; Moulaert et al., 2013; Salathé-Beaulieu et al., 2019). With regard to the depth of the intervention, this means: The first is mainly affirmative-adaptive, the second transformative.

The intervention presents two case studies on social innovation developed as part of the Horizon 2020 project "Social Innovation in Marginalized Rural Areas" (SIMRA). SIMRA attempts to analyse the impact of social innovation using quantitative and qualitative methods and, in particular, to highlight the important role of civil society as an innovator. These methods cover a wide range, from social network analyses to comparative analysis of different regional policies. The intervention is based on 211 cases from the SIMRA database, some dozen cases of in-depth studies at European level, including two case studies from the Swiss mountain region.

In the context of European peripheries, SIMRA defines social innovation as follows: "*The reconfiguring of social practices in response to societal challenges which seek to enhance the outcomes on societal well-being and necessarily include the engagement of civil society actors*." This definition of SIMRA is a compromise between the two schools on SI.

Two Swiss case studies

The Val Lumnezia is a lateral valley of the Anterior Rhine in the canton of Grisons, in the Alps. This Romansh-speaking valley was particularly isolated and marked by emigration. Thanks to an initiative of young craftsmen/entrepreneurs in the 1980s, the region has undergone a structural change from purely agricultural production to agrotourism specialisation. The innovators were not guided by a mass tourism strategy, but were among the first to cooperate with environmental NGOs for environmentally friendly tourism. The Val de Travers (canton of Neuchâtel) in the Swiss Jura is specialized in watchmaking and micro-industry. The crisis in the watch industry and the increasingly visible division between the mountainous and lakeside areas have led the cantonal administration to develop a concept of mobility and agglomeration-building for the entire canton, integrating local municipalities and companies into an institutionalised form. The two case studies were part of the SIMRA project design and included quantitative evaluation of detailed, guided questionnaires as well as qualitative semi-structured interviews. The fieldwork took place in the summer of 2018; the repondants were local actors involved in local initiatives which we had selected as typical examples of social innovation in mountain regions. The interview partners were typologized according their different roles in the process. The reports on methodology and results will be (and are already partly) published on the SIMRA website (see below). First journal papers have been already published (e.g. Melnykowych et al, 2018; Perlik, 2018).

Results of Swiss case studies

First, both examples show that social innovations in marginalised areas can trigger new development dynamics that contribute to reducing regional disparities, at least in the short term. However, social innovations often remain linked to certain actors or constellations of actors and lose their significance as soon as these constellations change. Social innovations therefore have a life cycle ranging from the crisis as a triggering event to its end. Long-term sustainable territorial development is therefore not guaranteed. This remains linked to favourable framework conditions for territorial balance, which should be guaranteed by institutions at national and supranational level.

Although social innovation is very often seen in relation to civil society initiatives, Switzerland's two examples show that the role of existing public administration institutions and private sector actors should not be neglected under any circumstances, provided that they are capable of change. Social innovation is always triggered by the reaction to the impact of a major crisis, which has developed between social actors before, with specific consequences in regions with low population density. These upheavals are often associated with personalities of individuals and a generational change in political or economic decision-makers. In the case of Lumnezia, it is the return of a new generation of professionals (craftsmen, entrepreneurs) trained outside the valley. In the case of Val de Travers, it was a new generation of heads of public services at the cantonal level whose ideas met at the time perfectly the changing requirements of the Swiss Confederation's New Regional Policy (NRP), just being developed. This concordance allowed a creative process for the implementation of new regional development concepts. Both case studies show the importance of changing constellations between political institutions, private sector actors and new civil society actors (Marini Govigli et al., 2019b).

Trajectories of social innovations

Due to the definition of SIMRA which has not established a normative model for "societal well-being" and because long-term success cannot be monitored in the project, trajectories cannot be measured by their success (e.g. regional growth). That, what is feasible to analyse: based on theoretical approaches, it is possible to select key factors recognized for divergent regional development. In a second step, the elaborated trajectories can be checked with the aid of the SIMRA database. Therefore, we have selected the following key factors:

Origin of the main actors

It is important to know whether the SI is triggered by the local population or whether the dominant actors are newcomers from outside from an urban context. The different motivations determine to what extent peripheral mountain areas base their ideas and strategies on an urban context or whether they search rather alternatives based on their local knowhow.

Origin of knowledge

Tacit knowledge offers a unique selling point and makes it difficult to copy regional innovations elsewhere. On the other hand external knowledge gives new inputs and might prevent paralysis, isolationism and regional decline through depopulation.

Type of innovators

Innovators may come from the public sector, the private sector, or they are new actors, not yet organized before (civil society). A combination of all three is also possible.

Depth of intervention

SI in peripheral regions are mainly adaptive. Not fundamentally new, but new in a specific context. As from adaptive character, these SI do not change the territorial hierarchies. Due to their low population density, peripheral areas in general have little potential for transformative SI, i.e. deeper change. There, where peripheral areas produce transformative SI, they may also stimulate the sustainable development of urban areas.

Dissemination of SI

In particular, the Anglo-Saxon school, which interprets the SI as the creation of social enterprises, sees the success of an innovation through its dissemination in other regions. But also innovations in institutional practices (such as participatory spatial planning) can also be disseminated, even though this dissemination is rarely measurable.

Benign or malign evolution

Since SIMRA is mainly interested in the positive effects of SI, its database does not contain any examples that have turned bad. However there exist certainly cases where the region is weaker than before after an SI initiative. These cases are rarely named as SI, so they escape analysis.

Preliminary results of trajectory analysis

In 173 cases (of 211 records of SI in SIMRA), the local actors are the initiators; in 37 cases they come from outside. In the majority of cases, they are based on local (105) or local and external (99) knowledge. External actors who exclusively use external knowledge appear only rarely in the database (6), but these cases may occur in reality even more often: for example, the neo-rural movement since the 1970s or the establishment of alternative tourism hostels run collectively by young urban people may be part of it (Kluvánková et al., 2019, forthcoming).

The depth of the intervention is generally adaptive: it is an adaptation of regional development strategies under the conditions of increased competition. However, this factor has not yet been definitively assessed; in addition, there are still often disagreements about classification. As an example for transformative SI can be considered initiatives for the integration of refugees in mountain regions (e.g. Borzaga and Galera, 2016; Perlik and Membretti, 2018). These are innovative today because since the end of the Second World War, the welcoming experience tends to become forgotten and isolation has become more and more the rule. The reception of people in poverty is seen as a transformative innovation because it resists the nationalist and regionalist tendencies that currently prevail.

The assessment of the dissemination factor is not yet complete due to the heterogeneity of cases. It is becoming more and more obvious that this factor only makes sense for social enterprises because only in cases like this do we have information about the dissemination.

There are no malign or toxic initiatives in our data collection. Rather, there are many examples of stabilizing regional decline. Although they did not reverse the fragile situation, their absence would have considerably worsened the position of the peripheral regions within the territory.

Discussion and conclusions

The trajectories were developed on the basis of theoretical approaches and the existing data base on social innovations. They cannot be used to measure the success of initiatives.

The term "trajectory" refers to the development of initiatives and general future options resulting from these initiatives. These options can be interpreted as follows:

- In most cases, local actors try to stabilize existing local structures based on their local knowledge but with the aim of capturing external expertise.
- If external actors trigger the SI, they rely on local knowledge. There are only a few cases where this is not the case. But even though we have not found in our database, cases in which external actors rely mainly on their own (external) knowledge, these cases exist.
- While local actors rely heavily on local knowledge, they give a signal for the pursuit of decentralised regional development with its own specificities and disadvantages. In the case of transformative SIs, this could also mean impulses for urban areas. If SI based on local knowledge does not succeed, there is a risk of decoupling between rural and urban areas.
- If actors rely heavily on external knowledge, they can bridge the gap between urban centres and peripheries. This allows them to cooperate better with urban areas, but they must ensure that they can defend their own interests against urban agglomerations.

Abstract

Thrift and Credit Cooperatives (TCCs) in Thailand are the biggest operation in terms of business volume. Their members are people having the same career and the same community. Their main purpose is to promote savings and provide loan for members. These research objectives were to 1) study the operation of TCCs in the northeast of Thailand, and 2) analyze the economic efficiency of TCCs in the northeast of Thailand. The study population was divided into 2 groups 1) TCCs members in the northeast of Thailand which comprised of 1,230 individuals and 2) TCCs committee and management staff of 9 TCCs. Purposive sampling technique was applied as the sampling technique. It turned out with the 400 samples and 18 samples of committee and management staff. Primary data were collected by questionnaires and focused group. The secondary data were collected from the database of Cooperatives auditing department. Ministry of Agriculture and Cooperatives. Data analysis was composed of descriptive statistics, Data Envelopment Analysis Model (DEA Model) and content analysis. The research found that 1) from last 20 years, all of 9 TCCs have operated their business with their good shape in terms of financial status which were assets, debts, capitals, income, expenditure, and profit. Most of the time, 2 main businesses of TCCs are saving and lending for members, 2) 6 out of 9 TCCs acquired the economic efficiency while 3 of them faced with economic inefficiency. According to the research results, TCCs whose face with economic inefficiency could have their own business strategies to improve themselves to achieve economic efficiency. Economic efficiency of TCCs also made members confidently and trustworthy.

Keywords: *Economic efficiency, thrift and credit cooperatives, northeast of Thailand*

Introduction

Cooperatives in Thailand, like in all developing countries, have been initiated by the government since 1915 with the prime aim of using as a means to improve the livelihood of small farmers. This is due to the increasing indebtedness problem resulting from farmers who were suffering from the shifting of the self-sufficient economy to trade economy. The natural disaster such as drought and flood even added further to create more chronic and severe indebtedness to the farmers. Consequently, they lost their farmland and becoming laborers and thus leaving their debts unpaid (Cooperative Promotion Department, 2019). The first cooperative in Thailand named Wat Chan Cooperative Unlimited Liability was established by the government on February 26, 1916, in Phitsanulok, following the Raiffeisen credit cooperative type with a single purpose of providing farm credit and being organized as a small village credit cooperative to help the severely indebted farmers. The success of this cooperative type in preventing many farmers' land from being foreclosed by the moneylenders led to the increasing number of small village credit cooperatives all over the country. The small credit cooperatives had prevailed in the country until 1938 other cooperative types then established in responding to the people's needs (Cooperative Promotion Department, 2019).

In 1966, the government-cum-credit cooperative-owned Bank for Cooperatives was reorganized to the "Bank for Agriculture and Agricultural Cooperatives" a state enterprise, functioning as a financial center of agricultural cooperatives including lending directly to individual farmers (Cooperative Promotion Department, 2019). In 1968 with the objective to strengthen the cooperative movement, the Government enacted the Cooperative Act, 1968, which allowed the establishment of the Cooperative League of Thailand, functioning as the apex organization of the cooperative movement. The said Cooperative Act also allowed for the amalgamation program which combined the neighboring small village credit cooperatives, paddy and marketing cooperatives, land improvement and land settlement cooperatives into a large scale cooperative at district level performing multipurpose functions and was officially categorized as agricultural cooperatives.

At present, the cooperatives in Thailand are officially categorized to seven (7) types, namely: 1). Agricultural Cooperative, 2). Land Settlement Cooperative, 3). Fisheries Cooperative, 4). Consumer Cooperative, 5). saving and Credit Cooperative, 6). Service Cooperative, and 7). Credit Union Cooperatives.

Thrift and Credit Cooperative (TCC) is one of seven types in Thailand. In this research, the researcher pays attention to TCC which could be explained as below:

Thrift and Credit Cooperatives are those whose members are people having the same occupation or living in the same community. Their main purpose is to promote savings among members and provide loans for productive investment.

Thrift and Credit Cooperative Objective, being a financial institution, the specific objectives of Thrift and Credit Cooperatives are aimed to: 1) Encourage thrift among members. To encourage the saving habit, the cooperative currently offers two types of savings and 2) Provide loan services to members. Members' shares and deposits comprise a significant part of the loan funds made available to members with interest charged usually at rates lower than that of the prevailing market rates. In general, thrift and Credit Cooperatives raise capital funds through shares, deposits, reserve funds, loan funds, and support fund or donations. In its essence, a cooperative belongs to its members. Effective and efficient management of the cooperative is ensured when members exercise their rights and responsibilities properly. The most important responsibility of the individual member in attendance at the annual general assembly (AGA). The AGA gives him/her the opportunity to protect membership rights, a fair sharing of benefits and monitor cooperative operations. It provides also a forum to determine general policies, elect committee members and assign tasks to further benefit all the members. Within the framework of cooperative principles, laws and regulations and procedures, members must discuss problems together, share ideas and exercise the right to vote on committees and meeting resolutions.

Thrift and credit cooperatives (TCCs) play a key role in Thailand. In this study, the researcher intensively aimed at the role of thrift and credit cooperatives operational efficiency in the northeast of Thailand. The study area was focused on Kalasin province. In this study, the researcher set up 2 research objectives as 1) to study the operation of Thrift and Credit Cooperatives (TCCs) operation in Kalasin province, the northeast of Thailand and 2).To analyze the economic efficiency of TCCs in Kalasin province, the northeast of Thailand.

Material and Methods

The study population was the total numbers of saving and credit cooperatives in 1,230 TCCs members in Kalasin province, the northeast of Thailand which were 1,230 individuals. Samples were collected from 1,230 thrift and credit cooperatives' members. Simple random sampling was applied as the sampling technique. It came up with 400 saving cooperative members selected from 9 TCCs members as the sample size. Along with 18 samples of committee and management staff.

In this study, there were both primary and secondary data were collected. The primary data were collected by questionnaire as the data collection tool. The content validity and reliability were tested. The index of item-objective congruence was equal to 0.725 while the conbrach's alpha was equal to 0.95. Focus group was also applied as a primary data collection tool. Secondary data were collected from the database of Cooperatives auditing department. Ministry of Agriculture and Cooperatives, the Royal Thai Government.

Descriptive statistics was applied as data analysis such as arithmetic mean and standard deviation. The operational efficiency of thrift and credit cooperatives was calculated by Data Envelopment Analysis Model (DEA Model) as well as content analysis. Data envelopment analysis (DEA) is a nonparametric method in operations research and economics for the estimation of production frontiers. It is used to empirically measure productive efficiency of decision-making units (DMUs). Although DEA has a strong link to production theory in economics, the tool is also used for benchmarking in operations management, where a set of measures is selected to benchmark the performance of manufacturing and service operations. In benchmarking, the efficient DMUs, as defined by DEA, may not necessarily form a "production frontier", but rather lead to a "best-practice frontier" (Cook, Tone and Zhu, 2014). DEA is referred to as "balanced benchmarking" by Sherman and Zhu (2013).

Data envelopment analysis or DEA is a linear programming technique developed in the work of Charnes, Cooper and Rhodes (1978). It is a non-parametric technique used in the estimation of production functions and has been used extensively to estimate measures of technical efficiency in a range of industries (Cooper, Seiford and Tone, 2000). Like the stochastic production frontiers, DEA estimates the maximum potential output for a given set of inputs and has primarily been used in the estimation of efficiency. However, again like the SPF approach, DEA also can be used to estimate capacity utilization (Färe, Grosskopf and Lovell, 1994). The Färe, Grosskpof and Lovell approach, however, seeks to determine capacity output, conditional on the fixed input binding production. This is the weak concept of capacity output offered by Coelli, Grifell-Tatje and Perelman (2001). The strong concept includes the weak concept, while the weak concept does not include the strong concept of capacity output. In addition, the weak concept avoids problems caused by particular functional forms and decreasing returns to scale---the Cobb-Douglas production function, which does not have an absolute mathematical maximum. Seiford and Thrall (1990) describe DEA in terms of floating a piece-wise linear surface to rest on top of the observations (i.e. envelop the data). More specifically, the key constructs of a DEA model are the envelopment surface and the efficient projection path to the envelopment surface (Charnes et al., 1995). The projection path to the envelope surface is determined by whether the model is output-oriented or input-oriented. The choice of input- or output-oriented models depends upon the production process characterizing the firm such as minimize the use of inputs to produce a given level of output or maximize the level of output given levels of the inputs. For the purpose of estimating capacity in fisheries, only the output-oriented DEA measures have been empirically estimated.

Results and Discussion

According to the research objectives, the researcher would present the research results following the research objectives as below:

1) The situation of Thrift and credit cooperatives (TCCs) operation in Kalasin province, the northeast of Thailand. The 9- study thrift and credit cooperatives limited in kalasin province shown that the maximum value of assets, debts and capital were 427,326,522.80 $, 261,581,841.17 $, and 165,744,681.64 $ respectively. Kalasin Establishment Thrift and Credit Cooperative Ltd had the maximum value of assets among others while Kalasin Teacher's saving and Credit Cooperative Ltd. had the maximum value of debts and capital. The maximum value of assets, debts and capital were 15,810.84 $, 189,734.38 $, and 84,104.67$ respectively. Non Sung Community Saving and Credit Cooperative Ltd had the minimum value of assets and debts while Kalasin Private School

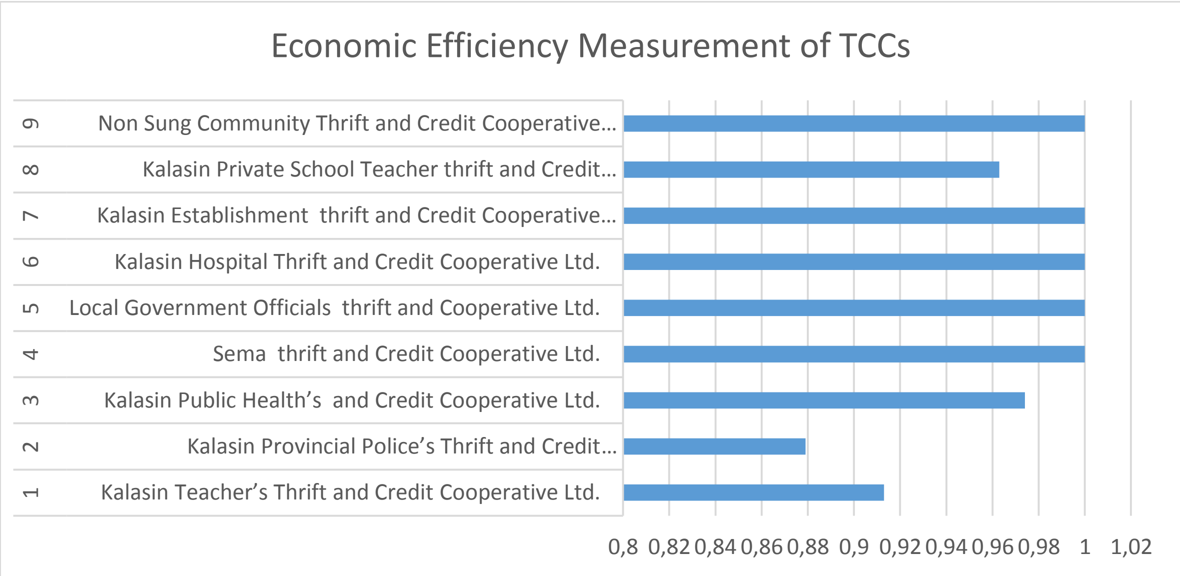
Teacher Saving and Credit Cooperative Ltd. had the minimum value of capital. The average value of assets, debts, and capital were 71,791,521.64 $, 43,230,871.46 $ and 28,599,299.86 $ respectively. The standard deviation of assets, debts and capital were 71,791,521.64 $, 43,230,871.46 $, and 28,599,299.86 $ respectively.

The 9- study saving and credit cooperatives limited in Kalasin province shown that the maximum value of income, expenditure, profit (loss), operational capital were 30,176,539.12 $, 22,322,328.04 $, 2,980,634.23 $, and 124,296,219.77 $ respectively. Kalasin Teacher's thrift and Credit Cooperative Ltd had the maximum value of income, expenditure, and operational capital while Kalasin Public Health's thrift and Credit Cooperative Ltd. had the maximum value of profit. The minimum value of income, expenditure, profit (loss), operational capital were 13,610.97 $, 17,767.40 $, 9,959.64 $, and 15,810.84 $ respectively. Non Sung Community Thrift and Credit Cooperative Ltd. had the minimum value of income and operational capital while Kalasin Private School Teacher Thrift and Credit Cooperative Ltd. had the minimum value of expenditure and profit. The average value of income, expenditure, profit (loss), operational capital were 30,176,539.12 $, 22,322,328.04 $, 1,793,605.02 $, and 124,296,219.77 $ respectively. The standard deviation of income, expenditure, profit (loss), operational capital were 3,007,623.33 $, 837,921.27 $, 2,169,702.06 $, and 39,421,067.41 $ respectively.

2.) Measurement the Economic Efficiency (EE) of Thrift and Credit Cooperatives in Kalasin Province. The overall economic efficiency score of TCCs in Kalasin province showed up in the 0.985. This meant that all TCCs in Kalasin acquired very high efficiency shown in Figure 1.

There were 9 thrift and credit cooperatives limited were measured operational efficiency (OE) applying the Data Envelopment Analysis Model (DEA Model). The results turned out that there 6 thrift and credit cooperatives limited met the standard score of EE which was 1.00. These were 1) Kalasin Public Health's Thrift and Credit Cooperative Ltd., 2) Sema Thrift and Credit Cooperative Ltd., 3) Local Government Officials Thrift and Cooperative Ltd., 4) Kalasin Hospital Thrift and Credit Cooperative Ltd., 5) Kalasin Establishment Thrift and Credit Cooperative Ltd., and 6) Non Sung Community Thrift and Credit Cooperative Ltd. Nevertheless, there were 3 out of 9 thrift and credit cooperatives limited acquired the standard score less than 1.00. This meant that these thrift and credit cooperatives had their operational performance under the standard.

Figure 1. Economic efficiency measurement of Thrift and credit cooperatives limited in the northeast of Thailand



Conclusions

Thrift and credit cooperatives (TCCs) limited in the northeast of Thailand played the crucial role in the rural areas in Thailand not only in the northeast of Thailand but also all over rural areas in Thailand. The role of TCCs Economic Efficiency in northeastern Thailand. According to the research results, there were 6 out of 7 of TCCs met the requirement of operational efficiency. This means that the operational efficiency score was less than 1.00. Since TCCs in the provincial area including in the study area perform as microfinance function. They were a provision of microloans to the middle and low-income class in Kalasin province, the northeast of Thailand and small business lacking access to banking and service. TCCs is the local microfinance institution in the local area which should be based upon the noble intention of local people. TCCs has still been the lifeblood in the local economy. In accordance with Begajo, T.M. (2018) who studies the role of thrift and credit cooperative in improving rural micro-financing the case of Bench Maji, Kaffa, Shaka Zones, Ethiopia. In addition, commodity developer had long understood the importance of local participation in the events and processes that shape community effective, democratic, and people-and-place-centered development strategies had the potential to achieve such participation (Majee, W. and Hoyt, A., 2011).

Abstract

Rapeseed mustard is an important oilseed crop of world with area of 36.53 million hectare average productivity of 2.05 tonnes per hectare and global production of 74.91 million matric tones. India is a global player in edible oil arena, being the 2nd largest importer, and 3rd largest consumer of edible oil as well as 4th largest oilseed producer. *Brassica rapa* (L.) and *Brassica juncea* (L.) (Czern &Coss) are the major cultivated oeliferous *Brassicas.* Its cultivation is facing some major constraints like non availability of quality seeds, poor soil healthnot being grown as sole crop, effect of major biotic and abiotic stresses and slower adoption of improved production technologies.Front line demonstrations (FLDs) being conducted under All India Coordinated Improvement Project on Rapeseed & mustard Research are playing an important role in mitigating the major constraints in rapeseed-mustard productivity. A large number of FLDs were carried out in farmer's field involving seven districts of eastern Uttar Pradesh region (Varanasi, Mirzapur, Chandauli, Sonbhadra, Ghazipur, Deoria and Jaunpur)for over three consecutive years i.e. during *(Rabi)* winter seasons of2016-17, 2017-18 and. 2018-19. Studies were carried out on overall effect ofuse of two improved varieties Giriraj (IJ-31) and NRCHB-101 over local variety 'Varuna' as well as the improved practices also including line sowing, proper weeding, spacing, Sulphur application along with the recommended dose of NPK, integrated disease and pest management and mechanized row sowing. The results exhibited remarkable increase in yield as well as NMR (Net Monetary Return) percentage by following improved Practices (IP) over Farmers Practices (FP).

Keywords: *Rapeseed-mustard, improved production technologies, NMR.*

Introduction

India is the 4th largest edible oil economy in the world and contributes about 10 per cent of the world oilseeds production, 6-7% of the global production of vegetable oil, and nearly 7 percent of protein meal. The major oilseeds production statistics of the World for the year 2016-17 includes a production of 549.98 million metric tons from an area of 234.57 million Hectare with the productivity of 2.34 metric tons per hectare. India ranks second in terms of area, i.e. 33.83 million Hectares but third in both production and productivity being 36.32 million metric tons and 1.07 metric tons per hectare, respectively. Rapeseed-Mustard is the second most important oilseed crop of India and plays a significant role in Indian economy by contributing about 27.8 % of the total oilseed production. Considering the World scenario, the important Rapeseed-mustard growing countries includes India, China, Canada, France, Poland, Pakistan etc. where India ranks third both in area and production of this crop. The average global area, production and productivity of rapeseed-mustard was recorded to be 35.37 million ha, 74.00 million tonnes and 2090 kg/ha, respectively in 2017-18 (USDA Circular series WAP 3-19, March 2019). In India, the average area of rapeseed-mustard was 6.02 million hectares with 7.92 million tonnes production and 1304 kg/hectare productivity during 2016-17 (Directorate of economics & Statistics, Govt. of India). The major mustard producing states are Rajasthan, Madhya Pradesh, Uttar Pradesh, Haryana, West Bengal, Gujarat, Jharkhand and Assam. Almost half (48.12%) of Rapeseed and Mustard is produced by only Rajasthan. Rapeseed-mustard is the second most important oilseed crop mainly grown in Rajasthan, Madhya Pradesh, Haryana, Uttar Pradesh, West Bengal and Gujarat. Rapeseed-mustard tops the list in case of vegetable oil with total contribution of 31% followed by soybean (26%). The combined area of *Kharif* and *Rabi* oilseeds during 2016-17 as per Government of India estimates is 282.22 lakh hectares and production of key nine oilseeds crops for the current year 2016-17 is estimated at 269.31 lakh tonnes compared with 203.41 lakh tonnes last year, showing 32 per cent rise.

The demand for vegetable oil in India in 2015-16 was around 235 million tonnes. This demand is met from domestic sources and imports. The domestic sources of vegetable oil are of two types viz. primary and secondary. Primary sources include Groundnut, Rapeseed (Mustard), Soybean, Sunflower, Sesamum, Niger seeds, Safflower, Castor and Linseed. Secondary sources include Coconut, Cottonseed, Rice bran, Solvent Extracted Oils and oils from tree and forest origin. Primary sources cover around 60MT of the total demand, while secondary cover 29 MT, thus making domestic supply to meet around 89MT of the total domestic demand. Of this, around 5MT is exported or used in industries. The Net domestic availability of Edible Oils thus remains around 86.37 MT and rest is met through imports. In 2015-16, India imported 148.20 million tons of edible oils. Thus, India has an alarming level of import dependency on oil. This makes it clear that a huge demand-supply gap exists and India is number one edible oil importer in the world. Since the productivity of India is way far behind the World's average and also with that of the country with highest productivity.

The name of Rapeseed mustard is used for oilseed Brassica, *Eruca* and *Sinapsis* which comes under the family Cruciferae or Brassicaceae. The oil content of the mustard seeds ranges from 38- 46% which is used as a cooking medium in Indian cuisine. Mustard oil possesses one of the best fatty acids profile, (low saturated fatty acids (8%), high monounsaturated fatty acids (70%) and alpha linolenic acid (10%). The Rapeseed-mustard cultivation is mainly rainfed and Oilseed Brassica (OSB) is a high nutrient demanding crop but mostly cultivated by small and marginal farmers in nutrient deficient soil of semi-arid regions. Continuous cultivation of OSB in such regions has resulted in stagnation of yield, increased cost of production and decline in factor productivity. This accounts for the main reason behind the low productivity. Poor soil health and lack of adequate quantities of soil macro and micro nutrients are also an important factor contributing to the same. The main reasons are insect-pest infection, disease incidence and poor technology transfer etc. Another important reason which cannot be ignored in the changing climate scenario is non availability of upgraded technology by scientists so that technologies could be transferred to farmer's field successfully. The adoption of recommended practices by the farmers is very low.

Under the scheme of Frontline demonstrations and other related activities of oilseeds funded under NMOOP by DAC&FW, Ministry of Agriculture and farmers' welfare, Govt. of India, over many years has been conducting FLDs under irrigated as well as rainfed conditions on Rapeseed-mustard. The Objectives of the FLDs was to find out gap between potential yield, demonstration yield, extension gap, and technology index.

Materials and methods

The FLDs were conducted for two varieties of Rapeseed-mustard viz. Giriraj and NRCHB-101 in the fields of selected farmers in Varanasi, Mirzapur, Chandauli, Sonbhadra, Ghazipur, Deoria and Jaunpur district over three consecutive years i.e. during winters of2016-17, 2017-18 and 2018-19. Studies were carried out on overall effect of use of two improved varieties Giriraj (IJ-31) and NRCHB-101 over local variety 'Varuna' as well as the improved practices also including line sowing, proper weeding, spacing, sulphur application along with the recommended dose of NPK, integrated disease and pest management and mechanized row sowing.The sowing was done in the first fortnight of October to first fort night of November.

Seeds and basic inputs were provided to the farmers through front line demonstration project. The farmers were guided and the crops were monitored by scientists from Institute of Agricultural Sciences, Banaras Hindu University, Varanasi in every stage of the crop development. The yield data per hectare were collected from both the demonstration and farmers practice by random crop cutting method. Table 1 shows the summary of the FLDs Conducted During 2016-19 and net monetary return and benefit cost ratio was calculated using formula:

Net Return = Gross return - cost of cultivation;

Cost of all inputs was cumulated as **cost of cultivation**;

Yield increase over farmers practices = $\frac{\text{Yield under improved technology}}{\text{Yield under farmer's practices}} \times 100$

Benefit cost ratio = Gross return / cost of cultivation.

Table 2 shows the particulars of materials and methodology followed in Farmers practice and Improved practices.

Table 1. Summary of the FLDs Conducted During 2016-19

Particulars	2016-17	2017-18	2018-19
Name of crop	Rapeseed-Mustard	Rapeseed-Mustard	Rapeseed-Mustard
Type of FLDs with numbers	Whole Package (30)	Whole Package (80)	Whole Package (100)
Name of varieties	Giriraj and NRCHB-101	Giriraj and NRCHB-101	Giriraj and NRCHB-101
Situation:	Irrigated Normal sown	Irrigated, Normal sown	Irrigated, Normal sown
Name of the districts covered	Varanasi, Mirzapur, Chandauli, Sonbhadra, Ghazipur, Deoria and Jaunpur	Varanasi, Mirzapur, Chandauli, Sonbhadra, Ghazipur, Deoria and Jaunpur	Varanasi, Mirzapur, Chandauli, Sonbhadra, Ghazipur, Deoria and Jaunpur
Date of sowing Range:	15/10/2016-10/11/2016	15/10/2017-10/11/2017	15/10/2018-10/11/2018
Date of harvesting	20/02/2017-10/3/2017	20/02/2018-10/3/2018	20/02/2019-10/3/2019

Table 2.Particulars of materials and methodology followed in Farmers practice and Improved practices

S.N	Particulars	Farmers Practice	Improved practices
1	Field preparation	1 deep ploughing followed by planking	One deep ploughing followed by 2-3 ploughing by harrowing planking
2	Variety	Varuna	Giriraj and NRCHB-101 (Improved varieties)
3	Seed rate	Not fixed	5 kg/ha
4	Seed treatment	No treatment given	1 kg seed with 2.5gms Thirum
5	Method of sowing	Broadcasting	Line sowing with spacing of 30cm x 15cm
6	Date of sowing	As and when field is available	Irrigated : 15^{th} October to 10^{th} November
7	Fertilizer dose	No fixed dose	Irrigated: 120,60,60,40; N,P_2O_5,K_2O and S
8	Weeding	Not done	One before 1^{st} irrigation and 2^{nd} after 1^{st} irrigation Pendimethalin 35EC @1 Kg a.i. in 800-1000 lit water per hectare as pre-emergence followed by hand weeding
9	Thinning	Not done	After 15-20 DAS
10	Irrigation	One pre-sowing irrigation and one irrigation after 30-35 DAS	Pre-sowing irrigation, and 2 irrigation one after 30-35 DAS and if there is no effective rainfall then 55-65 DAS
11	Disease and pest control	Not managed	As per need of the crops
12	Harvesting	At complete maturity	When 75% plants show physiological maturity

Results and discussion

Front line demonstrations (FLDs) being conducted under All India Coordinated Improvement Project on Rapeseed & mustard Research play an important role in mitigating the major constraints in rapeseed-mustard productivity. From Table 3 it is revealed that even though cost of cultivation from improved practice (25928.3Rs/ha) was more than the farmers practice (21372 Rs/ha) the net monetary return from the improved practice (47508 Rs/ha) was more than the farmers practice (36867.3 Rs/ha). The seed yield was more when improved practices were followed (20.9 q/ha) compared to the seed yield from farmers practice (16.3 q/ha). The results exhibited remarkable increase in yield as well as NMR (Net Monetary Return) percentage by following improved Practices (IP) over Farmers Practices (FP). Percentage yield increase over farmers practice (YIOFP) was significant and Benefit-Cost ratio (BC ratio) of improved practice (2.9) was found to be more than farmers practice (2.57). Increase in Net Monetary Return means there is increase in farmers' income henceforth apprehension in adoption of new technologies can be overcome. Positive effect of front line demonstration on Production, Profitability, and social impact on mustard cultivation was seen in the average status of mustard production in different districts of Uttar Pradesh.

Legend: IP: Improved practices, FP: Farmer's practices, COC: Cost of Cultivation, YIOFP: Yield increase over farmers practice, NMR: Net monitory return

Table 3. Results of Front Line Demonstrations conducted during 2016-19

Plate 1: Farmers field conducting the mustard FLDs.

Conclusion

The gap between the import and export can only be decreased only if there in increase in production and productivity. Increase in production and productivity can be achieved by adoption of new technologies and proper package of practices. Farmers should switch to cultivation of newly released, high-yielding, improved varieties with special characteristics such as tolerance to biotic and abiotic stresses in place of poor performing traditional varieties. This way they can get higher returns from same input area. One of the most important non-monetary input which is often ignored is sowing time: timely sowing of mustard results in higher yields due to escape from aphid attack, diseases and high temperature during siliqua development stage. Use of gypsum as a source for sulfur is also recommended since sulfur is one of the important constituents of mustard oil. The FLDs conducted over years suggest that if farmers adopt new technologies such as farm mechanization, line sowing with proper spacing, ensuring water availability at critical stages, integrated nutrient management, use of weedicides, integrated disease-pest management, there would be remarkable increase in the monetary return which ultimately helps to increase their income henceforth contributing toward growth in countries GDP and attaining self-sufficiency in oilseed production.

Abstract

"Food and Wine Tourism" is framed inside wider context of promoting and developing rural areas of a territory. The Wine Routes (alias wine roads) (WR) should allow the promotion of wine tourism and the enhancement of the rural territory, offering a particular "integrated system of tourism supply" that winds along with a specific territory and operates as a "center of multi-services". The Sicilian Wine Roads (SWR) have been established in 1999 to pursue these aims and to offer wine producers a different opportunity to diversify their offer. The Wine Roads (WR) are routes along the wine-growing territories that offer to tourists and visitors the opportunity to take advantage of different complementarian services to the wine, proposing a form of experiential tourism with powerful emotional involvement, as it combines gustative elements with naturalistic (e.g. wine landscape), recreational (e.g. socializing) and cultural ones. This study has the aim to know the current situation of the SWR, identifying their contribution to the Sicilian rural territory, highlighting strengths, weaknesses and treats that still exist. The results have highlighted that "Enjoy the experience of visiting the winery" was the main motivation for tourists, nevertheless, visitors appeared more experienced than in the past and aware of what wine tourism is.

Keywords: *Wine tourism, Sustainable toursim, Experiential Tourism, Motivational study, Rural Tourism.*

Introduction

Definitions of wine tourism abound as the discipline continue to evolve. The Wine Routes (alias wine roads) (WRs) should allow the promotion of wine tourism and the enhancement of the rural territory, offering a particular "integrated system of tourism supply" that winds along with a specific territory and operates as a "center of multi-services". In turn, these routes have been further promoted through the development of gastronomy and the relationship between culture, cuisine, and wine. In this sense, we can speak of a wine escape with the presence of vineyards, wine production activity and the wineries where the wine is produced and stored (Alebaki & Iakovidou, 2010; 2011). The "Wine Route", which combines landscape elements with experimentation and innovation activities, is a distinctive element and it becomes an extraordinary multiplier of value also for other regional products, as well as for the tourism system as a whole. According to other literature, it must be recognized that wine tourism involves both destination planning and marketing strategies (Getz, Dowling, Carlsen, & Anderson, 1999). In fact, the WRs promote a virtuous exchange between corporate interests and territorial policies and targets, aimed at enhancing the value of the territory, well aware that all this has a positive impact on the quality perception of the product by consumers.
The potential for wine tourism is enormous (Byrd et al., 2016), but the interesting issue is to focus on who are the stakeholders in the different wine territories and who stands to gain most, whether and when the effective potential will be realized.
In Europe, the first important studies on wine routes date back to 20 years needle. In one of their paper, Hall and Mitchell (2000) examined wine tourism in different regions publishing a

study on wine tourism on the Mediterranean area;in this study they argued that wine has always been part of the Mediterranean culture and it is an essential element of the so-called "Mediterranean Diet", which was awarded the designation of Intangible Cultural Heritage of Humanity in 2009 (Altamore et al., 2018; Lopez-Guzman 2014). Wine tourism in Europe has primarily been developed through the creation of WRs, with several countries implementing official wine routes (e. g., Greece, Italy, Portugal and Spain). However, in a continent like Europe with such a rich cultural heritage, wine routes are designed to be more than just an opportunity to taste fine wines (accompanied by the local cuisine). Indeed, these routes allow travelers to experience the social, cultural and environmental attributes that lend a distinctive character to each wine route, which although similar in terms of content, are each endowed with their own regional or geographical identity (Bruwer, 2003).

In Italy, the Wine Routes were regulated by a law since 1999, that financed also the birth of more than 179 territorial networks; unfortunately, only about 20 are fully functional and able to generate income while most of them are merely administrative decrees (Colombini, 2015). In the absence of an Italian Ministry of Tourism, wine tourism is regulated by the regions, but wine tourism and the wine routes have always fallen between two areas: agriculture and tourism with the result that neither of them is efficiently managed. The flow of tourists in Italy is observed without any scientific attention to the relationship between tourism in general and oenotourism. The data available for evaluating business generated by wine tourism is very vague and there are no in-depth studies (Colombini, 2015). All the experts of this sector refer to the Osservatorio del Turismo del Vino, drafted by Censis Servizi for the Associazione Città del Vino, which indicates a turnover of 3 to 5 billion of Euros.

Sicily, is one of the most important Italian wine producing regions, and also a particularly popular tourist destination, whose wineries receive about 500,000 visitors annually (Movimento Turismo del Vino, 2018; Associazione nazionale Città del Vino, 2016). The Wine Routes in Sicily propose an authentic and unreplicable identity: the Sicilian Identity alias the "Sicilianity" as a positive value. From a sociological point of view, the Sicilian WRs, are an "integrated system of tourism supply", they represent a paradigmatic case of "social capital" within a defined territory in which investments, experiences and politics must be shared in order to have a united territory wherein public and private subjects work together got the development of a territorial network of growth. The oeno-food-tourism itineraries have represented, therefore, in the last ten years, an important opportunity to trigger processes of participation in development projects of marked territorial importance in Italy. In Sicily, the Federation "Strade del Vino e dei Sapori" ("Wine and Food Routes") was founded few years ago to cluster most part of the existing Wine Routes with the aim to promote Sicilian excellence food products both in Italy and around the world, through an integrated tourist offer able to combine culture, nature, wine, and food. The members of the Federation are the Wine Routes and Wine cellars that aim to enhance the quality and typicality of their products closely linked to the territory of origin as well as "bed and breakfast", hotels, resorts, restaurants and also Municipalities that works for the valorization of their territory. Following recent studies that investigated motivations of wine tourists (Bruwer et al., 2018) and our previous studies (Chironi and Ingrassia, 2008), in this paper we present an investigation on the actual *profile* and motivations of the wine tourist in the Sicilian region of Italy. We wanted to know the role of the 12 Sicilian Wine Routes for the development of wine tourism. The objective was to know the current situation of the Wine Routes in Sicily, identifying the elements that characterize their strategic strength in promoting rural areas, but also their criticality. More particularly, we investigated the motivational factors that drive visitors-tourists to visit the cellars of the Wine Routes highlighting the current characteristics of wine tourism in Sicily.

Material and Methods

For this survey, the reference population is made up of the wineries associated with the Sicilian Wine Roads in 2018. The producers or managers of Marketing, Reception, etc. of the cellars contacted were asked, in advance, whether they were performing reception activities of tourists or visitors, even if not systematically, and whether they were willing to participate in the investigation. Only the wine cellars associated with the Wine Roads where the activity of receiving wine tourists or visitors was carried out and whose managers declared their willingness to collaborate in the investigation, which turned out to be equal to N=65 (census), were identified.

Questionnaire type

In each of the cellars surveyed (N=65), the owners or persons responsible for marketing, communication were interviewed in order to know the type of reception and the level of services offered, the target audience of visitors and the characteristics of the visit to the cellar. Moreover, for the study of motivational factors that lead a visitor/tourist to visit a cellar in Sicily, the interviewees were asked to give an order of preference to the 17 qualitative variables previously identified. Interviews were carried out using a specially structured questionnaire with closed questions, which was given by telephone interview or even sent by email if the interviewees had asked to fill it in at a different time. In addition to a first series of questions about the characteristics of the wine cellar and the visits, the questionnaire contained a list of 17 reasons (variable) for the motivational survey, which should be sorted in order of preference using a scale from 1 to 17 (ranging from 17 points).

For interviews with experts, a "question route" was used, usually structured in the event that qualitative surveys are carried out through Focus Group (Chironi et al., 2017; Ingrassia et al., 2017; Ingrassia et al., 2016) in order to maintain the same course of the discussion, while acquiring, from time to time, the different opinions of the interviews.

Factor Analysis

Factor Analysis (AF) and Principal Component Analysis (ACP) are two techniques used when the researcher's interest is to identify a smaller number of factors underlying a large number of observed variables (Bhunia, 2013). The purpose of the Factor Analysis is not to perfectly reproduce variance, as is the case in the Principal Component Analysis, but rather to simplify the correlation matrix so that it can be explained in terms of a few underlying factors (De Lillo et al., 2007). Therefore the components are real size, the factors are hypothetical dimensions, which are estimated from the observed variables (De Lillo et al., 2007). In this study, we are interested in highlighting the main factors that explain the phenomenon of wine tourism along the Strade del Vino Siciliane, and that summarize the different motivations that drive tourists/visitors to visit the wineries associated with the Roads. Therefore, in this case, the Exploratory Factor Analysis is able to better reveal the underlying dimensions of all the variables considered, since there is no pre-determined expectation as to which and how many factors will be extracted and, even if expectations are expected, these do not in any way influence the analysis (Ingrassia et al., 2016; Stevens, 2012). Following an in-depth preliminary study, the following seventeen motivational variables have been identified.It was not necessary to standardize the data beforehand, because the variables have the same units of measurement, that is, in this case, the values of the scale from 1 to 17 points, so we are imposing the same contribution of the original variables. Despite the fact that this study was carried out on a population, and not on a sample, it was, however, necessary to measure the goodness of the collected data; therefore, as usual in the case of Factor Analysis, the Kaiser-Meyer-Olkin Test (KMO) was applied, which suggests accepting index values at least equal to 0.7 or higher (De Lillo et al., 2007). Rotation is not always possible, but when it can be done, it redistributes the variance individually explained by each factor. The orthogonal rotation must be used under the hypothesis that the underlying factors are not correlated with each other, and, in this case, this hypothesis is acceptable because there is no theoretical reason to assume, in the beginning, that the factors can be correlated. We have therefore turned the factors using the orthogonal rotation technique called Varimax, which is the most widely used rotation technique in the literature (Landau and Everitt, 2004). The statistical software SPSS v. 21 has been used for processing.

Results and discussion

The profile of the tourist/visitor

One-third of the tourists/visitors to the cellars are of foreign origin, with German and American tourists prevalently, while two-thirds are Italian visitors. Visitors go in groups to some particular cellars, that is to say to those that have established a partnership with some tour operators or travel agencies over time, or that have a real activity of tourist reception in addition to the cellar, also made up of real resorts of high quality, thus welcoming tourists from Italy, Europe and the USA.

Usually, wine tourists who come to Sicily are of medium age, between 41 and 50 years old, graduates or graduates, carry out the profession of employees or freelance professionals, love to move in groups and visit the cellars as part of an organized trip. They can choose to make a "do-it-by-yourself" visit with the aim of spending a different day or weekend, but they always choose to move with other people. They are not always connoisseurs of wine, but they are still looking for an element in wine that makes them attractive to other factors that may be of different types and that complete the overall tourist "demand". Most tourists who travel along the Sicilian Wine Routes, to visit the cellars and taste wine, makes an organized trip. A large number of visitors make a simple one-day visit, usually on weekends, usually without a travel agency, but following a do-it-yourself organization, or through an association (of experts in the field or other), a club, a club, an institution or a club to which they belong. The interviewed visitors declared that the main characteristic to chose a wine cellar was the quality of the services offered (reception, cellar guides), hospitality and entertainment of visitors.

Results of the Factor Analysis

Table 1 shows the descriptive statistics relating to the motivational variables evaluated by the interviewees.

Tab.1 - Descriptivestatistics

Variables	Average scores	Std. Deviation
Experience the atmosphere of wine tasting in the cellar	2.45	1.368
Because they know the cellar and the producer directly	5.89	3.940
Know new wines and cellars	4.94	3.594
Get to know this particular cellar	3.50	2.690
They have heard a lot about the cellars and wines of "this area" and I want to know them personally	3.86	3.012
Buy wines in the cellar after tasting them to experience a different sensation from the one you try to buy it in a wine shop	6.14	3.023
Tasting wines and eating typical local foods	6.52	2.612
Have exchanges of ideas with the producer on labels and types of wine	7.94	2.612
Have exchanges of ideas with the producer on wine prices	10.27	1.810
Stay in company with other wine lovers	8.89	2.168
Pleasant aggregative moment with friends and/or relatives	11.11	3.107

Visit the beauty and landscape of the area and taste local products	9.63	2.186
For pure pleasure	12.59	2.029
For Hobby	14.70	1.508
For Business. job opportunities. conventions. etc.	14.73	1.504
It is a pleasant way to spend the weekend	15.08	2.318
Because the cellar is part of a Wine Route and the wine and food route is integrated with the territory.	14.02	3.124

Table 2 shows the total variance explained by the extracted factors and the cumulative variance. In addition, the graph of decreasing auto-values (Scree Plot Figure 14) also shows the identification of the number of useful factors, which in this case were six factors (KMO test equal to 0.871).

Table 2. Initial values of all components, unrotated and rotated factor weights, explained variance (total and cumulative of the six extracted components)

Factors	**Initialvalues**			**Unrotated factor weights**			**Weights of rotatedfactors**		
	Total	% of variance	% of cumulated variance	Total	% of variance	% of cumulated variance	Total	% of variance	% of cumulated variance
1	3.697	21.747	21.747	3.697	21.747	21.747	3.240	19.058	19.058
2	3.121	18.360	40.106	3.121	18.360	40.106	2.756	16.212	35.269
3	2.093	12.313	52.419	2.093	12.313	52.419	2.052	12.071	47.340
4	1.911	11.242	63.662	1.911	11.242	63.662	1.980	11.649	58.989
5	1.426	8.390	72.052	1.426	8.390	72.052	1.773	10.429	69.418
6	1.027	6.041	78.093	1.027	6.041	78.093	1.475	8.674	78.093
7	.840	4.939	83.032						
8	.692	4.070	87.102						
9	.605	3.560	90.662						
10	.429	2.526	93.188						
11	.343	2.020	95.208						
12	.257	1.513	96.720						
13	.240	1.411	98.131						
14	.135	.797	98.928						
15	.094	.556	99.484						
16	.081	.474	99.958						
17	.007	.042	100.000						

The Analysis showed that the first six identified factors highlight the following dimensions:

1) Aggregative

In this case, the first Factor (or component) highlights the highest factor coefficients for the variables *Pleasant aggregative moment with friends and relatives*, *Knowing new wines and cellars* and *Ashobby*, inversely related to *For business occasions*, and *Because they know directly the cellar and the producer*, and for this reason highlights the choice of spending free time in the company of other people known to discover wines and cellars of the territory.

2) Learning

This construct is characterized by variables, *Having exchanges of ideas with the producer on wine prices* and *For pure pleasure*, inversely correlated with *Staying in company with other wine lovers and tasting wines and eating typical local foods*, and highlights the consolidation of a trend that has been going on for several years now, namely the desire to visit the cellars to get closer to the world of wine, learn and know.

3) Oenotourism

The construct is characterized by variables *It is a pleasant way to spend the weekend, Visit the beauties and landscape of the area and taste local products* and *Live the atmosphere of tasting in the cellar* and for this reason, there is a strong tourist connotation in which it emerges the desire to know the territory under all aspects, including that of wine and food.

Factors 4,5 and 6 are those that most represent the size of an experienced and aware wine tourist, in fact, the variables outline the profile of a visitor who is increasingly interested in wines, experience, and atmosphere of tasting in the cellar and to personally know the territories of the wines consumed.

4) Pleasure/leisure

This dimension is characterized by variables, *For pure pleasure* and *Live the atmosphere of tasting in the cellar* and, therefore, it allows to identify the profile of a visitor who goes to a cellar for the pure pleasure of living the atmosphere of tasting, that he/she knows, and and so, the memory of this positive experience will push visitors to return to the same cellar or to a new one, to repeat the experience.

5) New experience

In this dimension the driving variableare, *Having exchanges of ideas with the producer on labels and types of wine*, inversely correlated with the variable *Buying wines in the cellar after having tasted them* to experience a different situation with respect to that of buying the wine in a wine shop.

6) Territory

The sixth and last factor is characterized by the variable *They have heard a lot about the wine cellars and wines of this area and want to know them personally* inversely correlated with *Because the cellar is inserted in a Wine Route* and it is possible to experience a food and wine route integrated with the territory.This dimension characterizes awine tourist who chooses to move, often autonomously, to discover the territory, along routes and roads.

Results of the Experts' interviews

According to the experts, there is still a very wide gap between the expectations of wine cellars associated with the Roads and the activities that the Wine Roads carry out for the purposes for which they are responsible. At present, the routes along the Wine Roads are still uncomfortable, difficult to identify, difficult to follow and without any form of signs or information signage. It is possible to affirm that the problem lies mainly within the Road Wine Associations which, for reasons of internal organization, are unable to operate as they should.

Short discussion

The analysis of the results showed that, certainly, all the dimensions extracted are characterized by a strong hedonic connotation. In fact, in each of these Factors, there are always one or more variables linked to the dimension of "Leasure/Pleasure" and the pleasantness that links the view to the tasting in the cellar.In addition, the results show that the main factors that lead visitors to visit the wine cellars associated with the Sicilian Wine Routes are not closely linked to the fact that the cellars belong to a Wine Route, but are instead the result of ongoing cultural and social phenomena, which show two main motivational lines, the first linked to wine and food tourism in general and the second more closely linked to pure tourism, characterized by tourists/visits. Finally, it is important to note that the fact that the cellars belonged to the WRs was not one of the important reasons that influenced the visitor in choosing the cellar. This confirms the results of the interviews with qualified persons who pointed out that the WRs are difficult routes to identify by visitors due to structural and infrastructural deficiencies and that the visitor becomes aware of the WR in which the cellar is located only after having arrived there. The critical element of the WRs that emerged from this study lies in the fact that today the WRs in Sicily have become only tools on the part of the associates, aimed at intercepting contributions or funding to carry out promotion and territorial communication activities, provided for by the Regional RDP measures, but not specifically aimed at what was the original purpose of the Legislator who designed and established the Wine Roads.

Conclusions

The main results of the research show that the tourists are highly satisfiedwith thewinery visitwhile highlighting the relationshipbetweenwine, local cuisine, and the growing interest of travelers in everything related to wine culture. Results of the Factor Analysis show the main factors that optimally explain the phenomenon of wine tourism in Sicily and highlighted the main motivations that drive visitors to visit the Wine Routes wineries that are: aggregation of wine lovers, learning of new wines, tourism, pleasure of a leasure experience, new experience, visit the territory. The study revealed that unfortunately the Wine Roads in Sicily are still less effective than those in other Italian zones or foreign Countries, because of many reasons linked to the poor interst of wineries and stakeholders to work for a common project of valorization of wines and territory. In order to improve the effectiveness of the Wine Routes in Sicily it would be necessary to detach oneself from the interests purely linked to the economic aspect (financing for communication activities) and return the lost identity of these routes, repositioning them as the Legislator had thought, i.e. as a tool for the valorisation and integration of rural territories around the Wine as a central element of the System. The main contribution of this study is the possibility to replicate the method applied in other similar cases. In addition, Public Bodies and Local Administrations can implement effective actions to improve structures and infrastructures. Cohesion around a shared project can be the best way to improve the Wine Routes in Sicily. A SWOT Analysis might be useful to complete this study.

MULTIFUNCTIONALITY, A STRATEGIC PILLAR FOR AGRICULTURE IN DEVELOPING COUNTRIES: AN EVIDENCE FROM NEPAL

Kumar BHATTA[1], Adriano CIANI[2]*

[1]Chiba University, Chiba, Japan

Abstract

The approach multifunctionality of agriculture in the developed countries is applied as a means of rural revitalization and economic circulation. Although farm diversification and diversification in the developing countries is much more crucial, in most of the rural areas of the developing countries, it is not performed, and it is delayed. In this regard, the main objective of this study was to explore the potentialities of the multifunctionality of agriculture to support the sustainable rural development in the framework of the sustainable development goals (SDGs 2016-2030) in the developing countries. The empirical study was conducted in two of the rural districts of Nepal called Nuwakot and Rasuwa. The authors intentionally selected these districts because it is one separate block at the northern part of the capital city Kathmandu and connected to China. Further, even though it is located in the nearby capital city, and the rural villages have high potentials for tourism activities, the farmers are still focusing on subsistence farming without getting benefits from tourism. Based on the macro data of Nepal government and field visit, we conducted a case study. The result explored that this block needed the external supports in terms of knowledge, technology, and more importantly, supportive policy. The federal and central government should give support to the farmers so that they can implement multifunctionality in their farms, which leads to sustainable rural development.

Keywords: *multifunctionality, circular economy, SDGs 2016-2030, sustainable rural development, Nepal*.

Introduction

Multifunctionality of agriculture is a hot issue for rural development, and many of the industrial countries practiced it (Ohe, 2001; Ciani *et al*., 2012; Ragkos *et al*., 2015). Recently, the European Union (EU) developed the concept of territory development through the multifunctionality of agriculture (Todorova and Ikova, 2014; Lehman *et al.,* 2009) which means not the only locality of the rural areas but also the areas of cities will prioritize where agriculture is the main occupation. Indeed, the small farmers not only in the developing countries but also in the developed countries are facing many problems like selling their products and the low price even if they could sell the products and which ultimately pushes them towards poverty. Therefore, the farm diversification to generate additional income for the farmers is necessary both in developed and developing countries.

The condition of farmers in developing countries is more serious than in developed countries. It is due to no or very low government support to the farmers (Yu *et al*., 2019), lack of adequate infrastructures and subsidies on the agricultural inputs, traditional farming system, conventional types of seeds used in the farms. These problems are causing low agricultural products and low farm income for the farmers. However, these problems can be utilized as the identity of that particular area and start the multifunctionality. If it is properly promoted, different tourism activities can be launched in that area, and income for the farmers will be automatically generated, and territory development will be implemented.

In this regard, this study aims to explore the possibility of multifunctionality as a pillar for the economic diversification and economic circulation in the developing countries. For this purpose, the authors decided to conduct a case study in Nepal because it is one of the developing countries, and this country can almost represent the characteristics of the other developing countries. Also, the farm diversification in Nepal is more necessary and possible because Nepal recently received the new constitution and got a stable government through the election. The elected government declared "Visit Nepal Year 2020" to double the current number of foreign tourist arrivals at the country and the total number of visitors is expected to cross 2 million in the year 2020. At this moment, exploring the multifunctional activities in the country, first of all, help to diversify the farm income and economic circulations in the rural areas, secondly, it provides additional tourism destinations for the visitors. Ultimately, multifunctionality of agriculture leads to poverty alleviation and SDGs implementation in the developing countries.

Literature review

The concept of multifunctional agriculture emerged in the last decade of the twentieth century in developed countries where the economic importance of agriculture was negligible, and the community was increasingly concerned with the quality of consumed food and the surrounding environment (Todorova and Ikova, 2014). In the meantime, several policies to support the multifunctionality of agriculture, e.g. agri-environmental schemes, started to be implemented in Europe (Lehman *et al*., 2009). Multifunctionality or multifunctional agriculture are terms used to indicate generally that agriculture can produce various non-commodity outputs in addition to food. It is associated with particular characteristics of the agricultural production process and its outputs:

- the existence of multiple commodities and non-commodity outputs that are jointly produced by agriculture; and that
- some of the non-commodity outputs may exhibit the characteristics of externalities or public goods, such that markets for these goods function poorly or are non-existent (OECD, 2003).

Multifunctional agriculture generates relatively much employment per additional unit of output; that is, the employment/production rate is higher in multifunctional agriculture than in primary agriculture (Heringa *et al.,* 2013). Multifunctional activities in many rural areas are providing positive benefits to the farmers (Ohe, 2007). For instance, pluriactivities in the hamlets of Japan helped to prevent the farmland from being abandoned (Ohe, 2001), it affected a range of social, economic and environmental aspects of life on the island of Cyprus (Ragkos *et al.,* 2015). Similarly, the total value of agricultural multifunctionality in Yangtze River Delta in China had increased by 23.2%, which was mainly attributed to a significant increase in food provision and cultural leisure values (Yu *et al*., 2019).

Due to the importance of multifunctional agriculture, in many countries, the multifunctionality of agriculture has been promoted. From the analysis of the territorial system of Antica Volcej in Italy, it has emerged an excellent propensity at diversification. Indeed almost 70% of the firms had at least one added activity to the classic production (Borrelli, 2016). As multifunctional activities contribute positively to the farmer, therefore, Thai citizens are willing to pay for changes toward multifunctional agriculture, as expressed in an increase of their monthly food expenses (Sangkapitux *et al*., 2017). Among the attributes of agri-environmental practices, "*organic agriculture in combination with agro-biodiversity conservation*" garnered the highest preference, followed by "*organic farming as single practice*" and "*Good Agricultural Practice combined with agro-biodiversity conservation*" was suggested for being promoted by the Thai citizens (Sangkapitux *et al*., 2017).

As the importance of the multifunctional agriculture is understood, Yu *et al*. (2019) suggested that the future land use policy should focus on both urban control and promoting agricultural multifunctionality to foster the sustainable development of agriculture in metropolitan agglomerations in China. Ongoing transformation practices, such as land consolidation, should aim to improve the biophysical and socio-economic functions of farmland (Yu *et al*., 2019).
Based on the presented literature, we can claim that multifunctional agriculture is important from different perspectives and it should be introduced in developing countries too. The concept of multifunctional agriculture should also be promoted in Nepal. Thus, we search for its possibilities in Nepal because of the no research on this topic.

Material and methods

Study area
As the central theme of this study is to explore the possibilities of multifunctionality of agriculture in the rural areas to diversify the economic activities in the developing countries. We chose Nepal because it is one of the developing countries, more than 2/3 of the total population are working in the agricultural sector however this sector is contributing less than 27% in the national GDP (MOF, 2018). Thus, the farm income for the Nepalese farmers should be increased, and diversifying farm activities is one of the ways of income generation for the farmers.
In this study, we mainly focused on two districts of Nepal called Nuwakot and Rasuwa; these districts are located on the northern side of the capital city Kathmandu and becoming a separate block. Nuwakot is the neighboring district of the capital city, and Rasuwa has a border with China, and these two districts are crossed by the Pasang Lhamu highway which is proposed as the parts of OBOR (One-Belt-One-Road) initiatives of China government (Bhatta, Itagaki and Ohe, 2019). Similarly, Nuwakot district is connected by Pushpalal Lok Marga (a highway, which connects east and west of the country focusing on the hilly regions). A proposed inter-country railway also goes from these districts. Thus, shortly, this area is going to be a transportation hub.
Further, these districts are famous not only for nature as well as adventure tourism of Langtang National Park and Singla trekking trails but also renowned for the religious attractions like holy lake Gosaikunda, and other 107 sacred lakes of Rasuwa district and Bhairabi Temple, Devighat Temple, Dupcheswor, etc. in Nuwakot district are the representative examples. There are many more popular religious as well as cultural and historical places in these districts. Also, the habitat for the red panda in Lang Tang National Park attracts the visitors. These attractions and accessibilities can be the potential sources of tourists in the diversified farm activities after its establishment in the rural villages of both districts.

Data and analytical methodology
For the completion of this study, two types of data are administered. The table survey and the secondary data was collected from the different websites of Nepal Government's authorized bodies such as the central bureau of statistics (CBS), Ministry of Finance (MOF), and Nepal Rastra Bank. The micro-level data were collected directly from the field survey in August 2017. A total of 64 farmers fully participated in the field survey. By the help of the village representatives, farmers were invited in a specific place for the study purpose, then a small lecture on agritourism development in the village was given to the farmers and individual farmers were interviewed. As this study is mainly qualitative, we applied mostly the descriptive analysis of the data and conducted a case study of the village based on the primary and secondary data collection.

Results and Discussion

Both Nuwakot and Rasuwa districts have a significant number of people working in the agricultural sector (Table 1). In Nuwakot, 97% of the household's primary source of income is agriculture, whereas, in Rasuwa, it is around 91%. This data clarifies that most of all the people of the village are somehow depending on agriculture, and their income level is not good enough. As they are farmers, they focus more on farming, and education was not their priority, which resulted in the lower literacy rate in both districts. Around 40% of the people are illiterate, and those who are literate have only some primary level of education. Female educational level is much lower compared to the male in both districts. Similarly, the number of female-headed households is only around one-fifth in both districts.

Table 1: Statistics of the two districts.

Item	Nuwakot	Rasuwa
Total farming population	264498 (person) 95.32% (percent) 53984 (holdings)	43798 (person) 87.30% (percent) 8504 (holdings)
Household whose main income is from agriculture	97.1%	91.30%
Literacy rate	59.8% (M=68.0%, F=52.4%)	59.80% (M=67.95, F=52.41)
Female-headed household	21%	22%
Household head is a farmer	51821 (95.98%)	8168 (96.04%)
Agricultural land area	32992 Hectares	4557 Hectares
Total forest area	43%	31.4%
Evergreen snow area	-	16.6%

Source: Central Bureau of Statistics - Nepal (2017).

The role the household head plays is essential for the multifunctional activity in agriculture. More than 95% of the household heads of both districts are farmers, and their main source of income is farming. Thus, we can assume that the farmers are willing to develop the multifunctionality of agriculture to increase their income. Based on the result of the previous study conducted by Bhatta and Ohe (2019), we can say that the farmers of the rural areas will be willing for the multifunctionality of agriculture because the authors presented that farmers of rural Nepal where agritourism does not exist were willing to establish agritourism in their ordinary farms.

Both districts have plenty of natural attractions, especially mountains and jungles. These jungles can be utilized for the major attractions in the villages. The buffer zone of Chitwan National Park is used for the jungle safari, Tharu cultural trail to the local communities is developed which increased the numbers of tourists in the nearby villages (Poudel, 2014). Similarly, the jungles and buffer zone of Lang Tang National Park can be used as a complementary tourist attraction for the tourists.

Our survey (Table 2) showed that at least one person from 45.3% of households is either working in foreign countries currently or had worked in those countries for more than one year as a temporary worker. The experience of the migrant returnee can be employed for the multifunctionality purpose because a study conducted by Bhatta and Ohe (2019) statistically proved that those who worked in the foreign countries more than one year are more likely to start agritourism in their home village. Working as a tourist supporter was also an additional supportive factor for the diversification of the farm activities as our survey shows that 87.5% of the farmers have experience working as a tourist's supporter. That means the farmers are already aware of the tourism environment, and they also know the pros and cons of tourism.

Only 54% of the farmers said they have enough farm products to sustain their life, which means the remaining 46% of the farmers need some extra income to run their daily life.

Table 2: Attributes of farmers.

Item	Percentage	Sample size
At least one person worked in a foreign country	45.3%	64
Experience working as a tourist supporter	87.5%	64
Sufficiency of farm products	54.0%	64
Interested into new jobs	50.0%	64
※Regular student	41.6%	334
Handicrafts	50.0%	64

Source: Field survey Aug. 2017.
Notes: ※includes the information of the family members of the respondents and sample size only for this variable is 334.

On the other hand, 50% of farmers said that they want to challenge new job, farmers who are willing to move towards new jobs can be employed in the multifunctionality of the farms. As a supplementary product of the farm, 50% of the respondents said that they are still producing some kinds of handicrafts in their homes. If we can monetize them, the young generation will also be attracted and contribute to sustainable development. Moreover, 41.6% of the total sample are regular students. Based on this data, we can expect that if the farms start generating money, the new generation will also be attracted to farm activities.

Table 3: SWOT analysis for the possibility of multifunctionality in the northern block.

Strengths • Plenty of attractions (natural, cultural, historical and religious) • Significant numbers of people are in agriculture • Some areas are performing specialized farming like rainbow trout fish farming, goat, yak farming and so on • Forest area and evergreen snow-covered landscape, Lang Tang National Park, evergreen snow-covered mountain range view	**Weaknesses** • Poor infrastructure • Small landholdings • Lack of coordination between the government bodies • Low educational level of the farmers
Opportunities • Connected to China and the capital city • Crossed by the national highway and proposed train league between Nepal and Japan • 3rd popular tourist destination in Nepal including two popular trekking trails and one cultural trail • Good geography (from the plain land to the mountain 7270m) • Ongoing transportation network development projects	**Threats** • Young people do not like to work in agriculture • Easy to go to foreign countries especially for the temporary job and payment is comparatively high • Fear of losing culture and tradition

Source: Authors elaborations based on data collection.

Conclusions

In this study, the authors first defined why multifunctionality of agriculture is a crucial pillar for developing countries, and later on presented how farm diversification is possible in one of the rural blocks of Nepal. The authors gave a case study based on both primary and secondary data and explored that the rural villages have the potential for multifunctional agriculture.

Also, they defined SWOT for the multifunctionality of farms in the villages and its possibilities.
This study explored that the rural block of Nepal has possibilities of multifunctionality of agriculture. The authors can claim that numbers of household heads working in agriculture is an opportunity. Similarly, farmers who are willing to challenge to start new works can be another opportunity. The available attractions (natural, religious, cultural, historical) support the additional activities in and around the territory and should be promoted from the tourism point of view.
Based on the result of this study, the authors suggest the following implications for the policymakers. For the multifunctionality of agriculture, the adequate infrastructure development, capacity building of the farmers should be done. More precisely, view towers in a different destination increase the numbers of visitors in the rural areas. The additional supportive activities can be developed in the nearby jungles, and the trekking and hiking in the snow-covered areas can be employed. The different villages can be connected in a single trail, and the agritourism trail can be developed where tourists can enjoy many different cultures and traditions of the diverse communities. For instance, the red panda trail, agritourism trekking trails, the multi-ethnic cultural trail can be developed by joining multiple villages in the single package according to their interests. This study deals only with the macro data, the micro-level survey, and the capacity of the farmers on hosting tourist and implementing multifunctionality should be the next step of the study.

Abstract

The present study aimed to identify the impact of the introduction of modern innovations of marine lighting in the Gaza Strip on the socio-economic aspects of the fishing sector. The study used the analytical descriptive method to identify the effects of marine lighting on the fishing sector. The study relied on the secondary and primary data collection, where the method of literature review related to the research subject was used to form a theoretical framework for the subject of the study. Moreover, the questionnaire was used as a tool to collect primary data: over the study population of 300 fishermen in Gaza city, 120 questionnaires were distributed and 85 valid forms were retrieved for analysis purposes. The most important result was the presence of a significant effect between the aspects of development in the field of marine lighting in the Gaza Strip, the size of fisheries production, and the cost of marine production. Moreover, marine lighting resulted in the development of different aspects of marine management, including the volume of fisheries production in the Gaza Strip of 0.50: the expansion in the field of marine luminescence and double use would contribute to increases in the volume of fish production by 50%. In addition, the expansion of marine lighting and the doubling of its use would contribute to the reduction of marine production costs by 65%.

Keywords: *fishing sector, marine lighting, development, Gaza Strip, production*

Introduction

Fishing is one of the most important activities within the Palestinian agricultural sector. Despite the limited fishing area and the low availability of land for aquaculture, fish stocks contribute to the production of food of the Palestinian people, as well as the absorption of a part of the labor force in the agricultural sector. Workers in the fishing industry in the Gaza Strip account for about 36 thousand people (Shawa, 2017, p. 31).

Since 2001, the Gaza Strip has suffered from a shortage of local production of fish, which has led to the inability to meet the local needs of fish and thus resulting in the decrease of local consumption of fish for the citizens of the Gaza Strip. The shortage was accompanied by a decrease in the Gaza Strip per capita consumption of fresh approximately 4.1 kg per year for 2016. To compare with per capita global fish consumption, the Food and Agriculture Organization of the United Nations (FAO) recommended that the individual should consume 13 kg per year of fish as a minimum, indicating a deficit in fish production accompanied by a decrease in the per capita share of fresh fish in Gaza Strip. Gaza Strip produced 3305 tons of fresh fish in 2016, while Gaza Strip imports amounted to 3998 tons of fresh and frozen fish to cover the deficit in local production (Shawa, 2017, p. 5).

The low volume of local fish production in the Gaza Strip is due to a combination of internal and external factors that directly affect harvesting. Perhaps the most important external factor is the limited area for fishing allowed by the Israeli occupation, which reaches up to 9 miles from the coastline. As for the internal factors, they are concentrated in the weakness of the capabilities and equipment necessary to carry out the fishing process on the one hand, and the lack of fishermen to the advanced experiences that allow them to practice the profession of hunting professionally on the other (Salman, 2017, https: //www.alaraby.co.uk). As the work of the fishing sector requires the fulfillment of a range of important aspects that are not applicable to the fishing sector in the Gaza Strip. The most important health examination procedures and certificates of competence and vocational training and others (International Labor Conference, 2004, p. 42). In view of this difficulty experienced by fishermen in Gaza Strip, a number of them have emerged as important innovations and innovators in the fishing sector. These fishermen have overcome many obstacles in the fishing process and in some cases have increased the productivity of this important sector and contributed to increasing their contribution to agricultural production in the Gaza Strip.

In this context, the process of developing novel or more distributed uses of the central lighting for marine fishing through the introduction of generators on the central ships and supply these ships with LED lamps is an important process to evaluate the technique consists in the distribution of light on small ships and boats that have become operational in the vicinity of the central energy source. This technology has been the most important alternative to the traditional techniques that were previously adopted and based on the use of small lamps working with kerosene and cooking gas. These comburents, however, are very expensive and limited the productivity of fish in the Gaza Strip (Nizar Ayyash, interviewed by Doaa Hussein, September 9, 2018). This study is considered important because it diagnoses the aspects of innovation and development in marine fishing supplies in the Gaza Strip and it shows their significant impact on the development of various maritime work within this sector.

Materials and methods

1. Scope of study

2.1 Spatial Limit

The present study was carried out on the State of Palestine. The Gaza Strip was targeted as one of the important components of the State of Palestine because it has a seacoast overlooking the Mediterranean Sea that distinguishes it from the rest of the Palestinian areas. The focus was on targeting Gaza city as one of the most important components of the Gaza Strip. The current research focused on the agricultural sector as one of the main productive sectors of Gaza Strip.

2.2 Time Limit

The present study targets the fishing sector in Gaza City during the year 2018.

2.3 Human Limit

Staff in the marine fishing sector have been the main component of the current study community, and technical professionals in the fishing profession have been targeted as the direct element engaged in central lighting technology.

2. Activity description

The research activity focuses on exploring the areas of innovation and development in the fishing sector, where the fisheries sector represents the most important branches of the Palestinian agricultural sector. The Palestinian agriculture sector faces a number of challenges related to the introduction of raw materials through the problems of agricultural infrastructure. Studies indicate that the Palestinian agricultural sector, specifically in the Gaza Strip, suffers from many structural weaknesses that led to a decline in the productivity of this sector. The contribution of fishing to the GDP decreased from 32% in the year 1994 to about 6% in 2017. These difficulties were associated with the fishing sector, which is an important component of agricultural food production. The fishing productivity is the focus of this research activity which monitors aspects of innovation for this branch of the agricultural sector. Monitoring the impact of the development of lighting on the productivity levels in the field of fisheries in the

Gaza Strip, as developed in this study, allows to achieve a number of sub-objectives, namely, this study allows to:

- Explain the reality of fish production in the Gaza Strip before the introduction of lighting technology and after the real use of this innovation.
- Understand the impact of the development in the field of lighting on the cost of marine products in the Gaza Strip.
- Identify the effects of development in the field of marine luminance on the social aspects of workers in the fishing profession in the Gaza Strip.
- Demonstrate the main implications of the use of creative thinking among fishermen in the field of marine lighting for fishing in the Gaza Strip.
- Provide a set of recommendations to the relevant parties in the fishing sector to develop local innovations and activate them in the fields of fishing in the Gaza Strip.

The Researcher relied on the exploratory approach and used the analytical descriptive approach to construct a clear vision about the effects of innovation and development in the field of sea fishing.

The dimensions of the study tool were limited to four different dimensions to study the effect of innovation in the field of marine lighting and its reflection on the reality of the fishing profession in the Gaza Strip. These dimensions included the following:

The first: Dimension of marine luminescence

This dimension includes the monitoring of the development aspects of the marine lighting used in the fishing process in the Gaza Strip. This dimension included a set of specialized questions that monitor the nature of the development process introduced by the fishermen in the use of electricity generation techniques necessary for the fishing process and the feasibility of this development and their professional preferences in this scope.

Second dimension: The productivity of fish fresh

This dimension includes monitoring the impact of the use of marine luminaires developed on the volume of fisheries production in the Gaza Strip. This dimension included determining the nature of the opinions of marine fishing professionals about the contribution of lightening in increasing the size of marine fishing and its reflection on the volume of fish production in the Gaza Strip.

Third dimension: Marine production cost rates

This dimension includes an objective assessment of the contribution of the development in the field of marine lighting to the cost of marine fishing. This dimension included a number of specialized questions related to the size of the cost of marine fishing, especially in relation to the lighting and fuel used before the introduction of new development techniques and the current reality after using innovative techniques in the field of lighting for fishing.

Fourth Dimension: Maritime Management

This dimension is an objective evaluation of the impact of marine research in marine management. This dimension includes a set of special questions that monitor these effects on improving the flow of fishing business, the extent and distribution of fishing activities, and the extent to which this technology contributed to Introducing administrative concepts in the fishing profession based on concepts of job skills to a central source of lighting that can be worked in its surroundings by various teams of fishermen.

These dimensions were based on the interrelationship between the various activities of innovation and their impact on the economic and social environment within the Gaza Strip. In addition, one of the most important aspects of innovation and development in the field of fishing in the Gaza Strip is the impact of this innovation on other economic sectors. For example, the sector involved in the development of the marine luminaires, that does not represent an important effect for other countries but is relevant in the Gaza strip where vast unemployment is a critical issue. However in the Gaza Strip environment, which lacks the means and equipment necessary for fishing as a direct result of the Israeli occupation of the Palestinian territories and the siege imposed on the Gaza Strip from the outside world, this development is an important innovation from the point of view of workers in the fishing sector and those responsible for organizing this important sector within the Gaza Strip. In order to determine the nature of this innovation and development in the field of marine lighting, the candidate relied on the use of the questionnaire as a tool to analyze the detailed aspects related to it, and to identify the direct and indirect effects of this innovation on the economic and social aspects of workers in the fishing profession. The candidate has tested the validity and reliability of the approach (questionnaire). The results indicate that the questionnaire has a high capability to describe measure or evaluate a target issue, and the high degree of honesty indicates the absence of methodological errors in the method. The questionnaire reflects the real concept and allows measuring it on an appropriate scale. While the stability means to what degree can rely on the study tool to ensure the same results in the repeated applications. If the use of another researcher for the same study tool under the same conditions will achieve the same results, indicates, for instance, a high degree of stability and repeatability of the approach (Jonathan Weiner, 2007). After conducting the tests for the honesty of internal consistency, which reflects the size of the correlation between the paragraphs (question questions) for each of the different dimensions of the questionnaire form (marine light, fisheries productivity, marine production cost rates, marine management). Questions are checked for availability by calculating correlation coefficients between the score of each paragraph and the total score of the dimension to which it belongs. This test found the internal consistency between the paragraphs and axes belong to them at the level of statistical significance 0.05, except for the sixth paragraph of the first axis and the first paragraph of the third axis where they were excluded from the analysis. Table (1) shows the result of this test used to measure the degree of stability (Jonathan Weiner, 2007). By calculating the correlation coefficients between the score of each paragraph and the total score of the dimension to which it belongs, allowed to test for the internal consistency between the paragraphs and axes that Belong to them at the level of statistical significance 0.05. Results indicate that the correlation coefficient was significant for all paragraph, except for the sixth paragraph of the first axis and the first paragraph of the third axis that, therefore, were excluded from the analysis. Table (1) shows the result of this test.

Table 1. The validity coefficients illustrate the internal consistency of the Dimension study

First dimension: central lighting					
Paragraph	Coefficient of correlation	Level of significance	Paragraph	Coefficient of correlation	Level of significance
A1	*0.752	0.000	A7	*0.248	0.022
A2	*0.474	0.000	A8	*0.739	0.000
A3	*0.680	0.000	A9	*0.354	0.000
A4	*0.700	0.000	A10	*0.604	0.000
A5	*0.790	0.000	A11	*0.493	0.000
A6	0.171	0.117			
Second dimension: The productivity of fisheries			Third dimension: Marine production cost rates		
Paragraph	Coefficient of correlation	Level of significance	Paragraph	Coefficient of correlation	Level of significance
B1	*0.494	0.000	C1	0.202	0.065
B2	*0.779	0.000	C2	0.692*	0.000
B3	*0.609	0.000	C3	0.644*	0.000
B4	*0.658	0.000	C4	0.749*	0.000
B5	*0.718	0.000	C5	0.605*	0.000

Fourth Dimension: Maritime Management		
Paragraph	Coefficient of correlation	Level of significance
C1	0.826*	0.000
C2	0.826*	0.000
C3	0.779*	0.000
C4	0.795*	0.000
C5	0.770*	0.000

*significance at the level of 0.05

The stability of the study instrument (the questionnaire), was measured by the Alpha Cronbach and Jattman indices for the midterm segmentation that was calculated and reported in Table 2. The values of the Alkronbach coefficient ranged between the dimension of the study (0.481 - 0.858). This indicates that there is a good degree of consistency in the data collected from the sample. It is, therefore, possible to rely on it, analyze it, interpret its results and disseminate it to the study community.

Table 2. Results of tests of the stability of the study Dimension

Dimension		Number of items	Cornbrash's Alpha	Split half Reliability
	First dimension: central lighting	11	0.759	0.868
	Second dimension: the productivity of fisheries	5	0.661	0.569
	Third dimension: Marine production cost rates	5	0.481	0.621
	Fourth Dimension: Maritime Management	5	0.858	0.885

As for the statistical description of the individuals of the sample of the study based on personal data, the results showed that most of the workers in the sector of fishing in the category non holders of university degrees, as 74.8% have obtained degrees below the secondary certificate, While the proportion of educated class of holders of scientific degrees working in the profession of fishing 12%. It is noted that the sample members of the study of workers in the profession of marine fishing are the owners of over ten years' experience, where this group accounted for 46% of the study sample. In addition, most of the workers in the fishing profession under the age of 40 years, which accounted for 59.9% of the sample which is associated with the nature of maritime work, which requires a high physical effort compared to other occupations, Finally, most of the study sample consisted of married family members as the table (3).

Table 3. The statistical description of the sample of the study according to personal information

Demographic data		Total (N=85, P= 100%)
Age	Less than 30 years	(39, 45.9%)
	From 30 years to less than 40 years	(20, 23.5%)
	From 40 years to less than 50 years	(11, 12.9%)
	50 years and over	(15, 17.6%)

Marital status	Married	(60, 70.6%)
	Single	(21, 24.7%)
	Widowed	(3, 3.5%)
	Absolute	(1, 1.2%)
Years of Experience	1 to less than 5 years	(17, 20%)
	5 years - less than 10 years	(22, 25.9%)
	10 years - less than 15 years	(15, 17.6%)
	15 years and over	(31, 36.5%)
Qualification	Diploma and less	(9, 10.6%)
	BA	(1, 1.2%)
	Postgraduate	(1, 1.2%)
	Other *	(74, 87.1%)

* Other educational qualifications (elementary, preparatory, public high school)

Results of analysis of axes of the study tool

The results of the analysis of the axes and the dimensions of the questionnaire indicate that there is a positive trend in the respondents' opinions on the importance of development in the field of central lighting and its various implications on both the productivity of the fishery and its associated costs. Moreover, respondents indicate that central lighting contributes to the development of marine management practices associated with the more benefits obtained by the innovation. Table (4) Explains this.

Table 4. Trends of Respondents on Question Areas

Dimension	Number of items	M	SD	RII	T	Rank
First dimension: Central lighting	10	4.04	0.52	80.8%	*18.4	4
Second dimension: The productivity of fisheries	5	4.41	0.48	88.3%	*27.0	1
Third dimension: Marine production cost rates	4	4.37	0.53	87.4%	*23.5	2
Fourth Dimension: Maritime Management	5	4.28	0.66	85.6%	*17.7	3

Hint: M=Mean of answers, RII=Relative Importance Index ((Mean/5) *100%), SD=Standard Deviation., T = statistics of one sample T-test about (3), and *sig = significance of the test

Table 4. Shows that 80.8% of the participants show positive tendencies towards adopting the areas of development in the marine lighting due to a number of considerations related to the contribution of this technology including the belief that this technology will simplify the work procedures and increase the economic return. The results showed that 88.3% of the workers in the field of marine fishing believe that the introduction of lighting technology central will contributed to increasing the productivity of fish wealth, and 87.4% of fishermen believe that the development and use of central lighting will contribute to the reduction of costs of marine production. Finally, 85.6% of the workers in the marine fishing profession believes that the use of central lighting has contributed to the development of aspects of marine management.

Testing hypotheses

The effect of the independent variable (central light) on the dependent variables (fish production, marine production costs, and marine management) was studied using the simple linear regression model. The null hypothesis is statistically tested (H), which assumes no significant effect on the alternative hypothesis (H1). The test result is judged based on the value of the measured significance level of the test (Sig) where the null hypothesis is rejected and the hypothesis is validated if the Sig is less than 0.05. It is said that the test with the null hypothesis is accepted if the value of Sig is higher than 0.05 and Nesting when there is no statistically significant effect. Table (5) shows the results of the estimation of the simple linear regression model.

Table 5. Results of estimation of the simple linear regression model

Independent variable "Central light"								
#	Dependent variables	Pearson the correlation coefficient (r)	Fixed limit (a)	Regression coefficient (B)	Coefficient of determination (R2)	The quality of the model at level 0.05		
						F	Level of significance (Sig.)	The result
1	Fisheries productivity	0.54	2.357	0.508	0.307	36.82	0.000	Significant
2	Marine production cost rates	-0.639	1.732	-0.655	0.409	57.39	0.000	Significant
3	Maritime Administration	0.587	1.307	0.735	0.345	43.12	0.000	Significant

* Significant at level 0.05

The first main hypothesis

The first main hypothesis is that "There is a statistically significant effect at the level of significance ($\alpha \leq 0.05$) in the central lighting on the production of fish wealth in the Gaza Strip,"

The results of the analysis of regression coefficients indicate that the doubling of the use of central lighting technology from the current situation will contribute to an increase in the productivity of fish stocks by 50.8%. Results indicate that there is a linear correlation between the central lighting and the productivity of fish wealth in the Gaza Strip with a correlation coefficient of 0.554. It is important to note here that the level of significance of the F-Test was 0.000, which is less than 0.05. A simple linear regression that measures the effect of the central luminance, thus, indicate a significant effect on the fish wealth due to the central light variable at the level of significance 0.05.

This finding confirms the validity of the first hypothesis which states that "there is a significant statistical effect at the level of significance ($\alpha \leq 0.05$) in the central lighting on the production of fish wealth in the Gaza Strip,”

The second main hypothesis

The second main hypothesis is that "There is a statistically significant effect at the level of significance ($v \leq 0.05$) in central illumination on the cost of marine products in the Gaza Strip,”

Table 5 shows a positive effect of the development process in the field of marine luminance on the reduction of the costs of marine products in the Gaza Strip. The results of the analysis of regression coefficients indicate that the doubling of the use of the central lighting technology from the current situation will contribute to reducing the costs of marine production by 65.5%, there is a linear correlation between the central lighting and marine production costs in the sector (correlation coefficient 0.639). It is important to note here that the level of significance of the F-Test was 0.000: this indicates the significance at the mean level of 0.05 of the simple linear regression model, which measures the effect of the central illumination on marine production cost rates. This finding confirms the validity of the second hypothesis which states that "There is a statistically significant effect at the level of significance ($\alpha \leq 0.05$) in the central illumination on the cost of marine products in the Gaza Strip."

The third main hypothesis

The third main hypothesis is that "There is a statistically significant effect at the level of significance ($\alpha \leq 0.05$) in the central illumination of the marine administration in the Gaza Strip," The results of the analysis of regression coefficients indicate that the introduction of central lighting technology has contributed to the development of the management practices of the marine fishing sector. As the doubling of the use of this purification from the current situation will contribute to the positive increase of the administrative practices related to maritime work, which will contribute to the development of these practices by 73.5%. There is a linear correlation (Pearson coefficient 0.587) between the central lighting and marine management in the Gaza Strip. It is important to note here that the level of significance of the test (F-Test) was (0.000) which is less than the level of 0.05, and this indicates the significance of the simple linear regression model.

This finding confirms the validity of the third hypothesis which states "There is a statistically significant effect at the level of significance ($\alpha \leq 0.05$) in the central illumination of the marine light in the Gaza Strip,"

Conclusion

Gaza Strip suffers from a lack of local production in fish, which has led to the inability to meet the local needs of fish; this developed into a reduction in the consumption of domestic fish production for the citizens of the Gaza Strip, accompanied by a decrease in per capita consumption of fresh fish meat per year compared to per capita world level. The annual per capita fish population in the Gaza Strip is about 4.1 kg for the year 2016. The Food and Agriculture Organization of the United Nations (FAO) recommended that the individual should consume at least 13 kg per year of fish.

There are a number of the main reasons for the decrease in the size of the local production of fish in the Gaza Strip, which include the limited area of fishing allowed by the Israeli occupation (limited to 9 miles from the coast), as well as the poor capabilities and equipment to carry out professional fishing.

The results showed a positive trend in the respondents' opinions on the importance of development in the field of central lighting and its various implications on both fish productivity and related costs, as well as its contribution to the development of marine management practices associated with this development.

The development of marine luminance is one of the important innovations at the level of the Gaza Strip, which contributed to the increase of the catch of fresh fish by 50% Where the quantities of production increased from 1,252,353 kg in 2010 to 2,504,706kg in 2015, according to statistics issued by the General Directorate of Fisheries in the Ministry of Agriculture in the Gaza Strip. The development of marine lighting techniques has contributed to the economic empowerment of marine fishing professionals in the Gaza Strip by increasing their income rates by between 30-50%, which supports the overall sustainability of work in the maritime sector. There is a significant statistical significance for innovation and development in the field of marine lighting on the volume of fisheries production in the Gaza Strip, as doubling the use of lighting technology from the current situation is believed to contribute to raising the productivity of fisheries by an average of 50.8%.

Abstract

The current paper intends to present the non-agricultural rural economy from Romania. Following the end of the centralized communist economy, Romania still lacks a private sector strong enough in order to ensure production and services at an appropriate level. That is why the financing of non-agricultural activities through National Rural Development Programme (NRDP) was one of the requested financing lines by the beneficiaries. For that purpose, the present paper intends to present the situation of the European funds available for the financing of non-agricultural activities for the 2014 – 2020 financial period using the publicly available information. The financing line analysed is the Sub-measure 6.4. Investments in the creation and development of non-agricultural activities. The paper would use a quantitative method in order to emphasize the interest of potential beneficiaries toward this type of activities. That would provide enough empirical evidences concerning the interest of potential beneficiaries of the financing.

Keywords: *NRDP, non-agricultural activities, financing, Sub-measure 6.4.*

Introduction

Traditionally the agriculture has formed the mainstay of rural economic activities, but this has changed in the second half of the twentieth century toward a much more balanced and diversified economy as more and more labour was driven out of the agricultural sector into employment in alternative sectors (Smit et al., 2015). Rural economic activities in Romania are very little diversified, the economy being dominated and dependent on agricultural activities. Non-agricultural activities are relatively under-represented, being dominated by the primary sector, mainly related to the exploitation and processing of natural resources (Gavrilescu, 2006). As far as the business environment is concerned, it is poorly represented in rural areas. Generally it can be noticed that after the destruction of the local economy specific to the communist regime, it has not emerged a strong enough private sector in order to take over the labour force and to ensure production or services at an appropriate level (Stănică, 2016).

The development of the non-agricultural enterprises sector in rural areas is a priority for Romania, as this could reduce the rural under employment, improve the use of local resources, increase the incomes in rural areas, and ensure a higher standard of living for the rural population (Kerekes et al., 2010). Rural development in Romania has been and is one of the most debated topics since the pre-accession period in the context of the Common Agricultural Policy (CAP), namely of the support that our country had benefited and still benefits through the 2nd Pillar, that of rural development, support related to the National Rural Development Programmes (NRDP) funded through the European Agricultural Fund for Rural Development (EAFRD). These ambitious programmes of high complexity, mainly financed by the EU, aim at stimulating the development and the territorial cohesion. Referring to the least developed regions in Romania, it will be rather an effort to stop the potential growth of disparities (Dachin, 2008).

The rural areas development in Romania and the other European countries can only be achieved on sustainable principles, in agreement to new challenges of contemporary civilization. This development pattern needs, however, adequate public policies, based on reality knowledge and adequate implementation (Burja and Burja, 2014). For developed communes that are economically and socially connected to nearby cities, the problem of dependence on agricultural activities seems to be overcome, many of which already having diversified economic activities, and the trend for the next period is to accelerate these processes (Mihalache, 2013). The financing of non-agricultural activities within the NRDP 2007-2013 and 2014-2020 by the related measures and sub-measures was one of the most requested directions by the potential beneficiaries of these types of funds, even though between the two programs had appeared a series of changes concerning the type of activities considered eligible for funding, respectively of the non-reimbursable support.

In the 2007-13 financial exercise, according to a scientific paper (Mack et al., 2018), it is found that: public support for business creation in non-agricultural activities (e.g., the public encouragement of tourism activities) has the strongest positive effect on rural vitality of all analysed measures. A healthy and diversified rural economy offers job opportunities outside of farms as well as social, economic and cultural services that attract and retain people in rural areas (Kerekes et al., 2010). In Romanian rural areas, entrepreneurship still encounters a large number of vulnerabilities and there is an important need to create the means for the rural entrepreneurs to have access to finance, professional advices and support and to benefit from a better and modernized infrastructure (Dan et al., 2017). The lack of a realistic vision of the future of the Romanian village, of the new occupations and qualifications required in the process of diversification of activities - to establish a multifunctional rural development - is becoming more acute (Dona, 2010).

Taking into account the aforementioned, the paper presents the analysis of the situation of the European funds related to the European Agricultural Fund for Rural Development (EAFRD) available for non-agricultural activities in the multiannual financial framework 2014-2020 up to the present moment. The analysis was made to highlight both the interest of rural applicants for starting a non-agricultural activity and to diversify their activity at the level of agricultural exploitation, depending on the total value allocated to Sub-measure 6.4 and the possibility of financing these activities under NRDP 2014-2020, as the main source of European non-reimbursable financing.

Material and Methods

The aim of the present paper is to present the situation of the European funds related to the sub-measure 6.4 *Investments in the creation and development of non-agricultural activities*, a sub-measure financing both the creation and the development of non-agricultural activities in the rural area, in the 2014-2020 financial exercise, funds from which Romania benefits through the Pillar 2 of CAP that of Rural Development.

Its elaboration was based on the official information provided by the Agency for Rural Investment Financing (AFIR) and the Ministry of Agriculture and Rural Development (MADR) through the documents available online on the websites of the two institutions. At the same time, these information were corroborated with the information related to the National Program for Rural Development 2014-2020 (NRDP - version IX, January 2019), regarding the sub-measures related to the financing of non-agricultural activities, namely of the value allocated within the framework of the entire financial exercise and of the non-refundable support as its intensity, in the rural areas within the context of the CAP and of Romania's integration in the EU.

As indicators used in the study, we mention the following:

– The value of the funds allocated for financing the non-agricultural activities;

- The number of application sessions for the projects for the 2014-2020 multiannual financial framework;
- The number of financing applications submitted, the number of financing applications accepted for funding;
- The number of signed contracts, the number of finalised contracts;
- The share of projects related to the investments in the modernization or the establishment of agro-touristic boarding houses.

The method used in the present study is a quantitative one and it was intended to emphasize first of all the interest of the potential beneficiaries towards this type of activities, namely the development of non-agricultural activities in rural areas. At the same time was followed the analysis of the number of projects that were contracted and also finalized in the timeframe analysed, in order to highlight the real interest of the applicants who became beneficiaries of European non-reimbursable funds for the diversification of activities at the level of the agricultural exploitation. At the same time was done a literature review concerning the speciality literature on non-agricultural activities and the importance of this type of activities in the real evolution of rural area both in Romania as an EU Member State and at EU level.

Results and Discussion

The sub-measure that was analysed in the present study, the sub-measure related to NRDP 2014-2020 that financed the non-agricultural activities is Sub-measure 6.4 *Investments in the creation and development of non-agricultural activities*. Sub-measure 6.4 aims (AFIR, 2017): Stimulating the business environment in the rural areas;

- Increasing the number of non-agricultural activities carried out in rural areas;
- Development of activities of the rural population;
- Reducing the differences between rural and urban areas;
- Diversification of economic activities of farmers or members of agricultural households by practicing non-agricultural activities in order to increase incomes and create alternative occupations.

According to the guidelines in the Applicant's Guide, concerning the areas of diversification, we mention as eligible the activities of production, handicraft, tourism, services providing, the production of pellet and briquettes of biomass (AFIR, p.4).

One of the main changes in the current financial exercise for this type of sub-measure is the one regarding the financing of the types of tourism activities compared to the previous financial exercises, i.e. the strict financing of the agro-touristic accommodation services, thus excluding the financing of the establishment of the tourist boarding houses, and this agro-tourism activity is seen as a diversification of the agricultural activity at the level of the exploitation. The emphasis is placed on the possibility of diversifying the sources of income of farmers, and also on the possibility that the young people studying in this field will return to rural areas to take care of this kind of activity, and then to take over the family's holding, thus bringing an added value both to the activity carried out and to the community in which they live. The aim of the sub-measures that finance the non-agricultural activities in rural areas is also to repopulate these areas, to make them attractive for young people studying in the cities.

Taking into account the above, the fact that the financial demand of sM6.4 was a very high one, supports the need to advocate further for the development and the diversification of activities in the rural areas in order to talk about rural development as an EU member state.

As a result of the analysis we made concerning sM6.4, it transpired that from the moment of opening the financing under the NRDP 2014-2020, there were 3 sessions for receiving projects for sM.6.4, sessions whose assigned values had reached the threshold allocated per total under the program, as shown in table 1.

Table 1. Sessions for submission of applications for funding sM.6.4 in the NRDP 2014-2020 and the total value of the projects submitted for financing

No.	Session No.	Allocated value (euro)	Value per session/ Total value %
1	sM 6.4 – 01/15 – 30.10.2015	57.214.935	32
2	sM 6.4 – 02/16 – 30.11.2016	85.000.000	48
3	sM 6.4 – 01/17– 31.07.2017	35.000.000	20
4	Total value concerning sM 6.4 in accordance with the announcements of project demands	177.214.935	100
5	Total value allocated in accordance with NRDP 2014-2020	166.503.969	106,43
6	Total value of submitted projects	423.635.360	254
7	Total value of submitted projects – total value allocated	257.131.391	154

Source: Own calculations after Archives of Projects Submission Session under the NRDP sub-measures 2014-2020, www.afir.info

From the above mentioned it is noted the interest of the potential beneficiaries regarding the diversification of the activity carried out at the farm level by requesting funds for non-agricultural activities, the funds available for the entire period being requested during the three submission sessions carried out between October 2015 and July 2017. It can be seen from Table 1 that the total value of the projects submitted for financing is 154% higher than the amount allocated for the whole financial exercise.

Table 2. The situation of the projects submitted, selected, contracted, finalised and cancelled at 11.04.2019 related to Sub-measure 6.4

Date of the implementation stage	Submitted projects		Selected projects		No. of selected projects / No. of submitted projects %	Projects under contract							% cancelled projects / projects under contract
						Projects under contract (ongoing and finalised)		*Finalised projects*		*Finalised projects out of projects under contract %*	Cancelled projects		
	No.	Value Euro	No.	Value euro		No.	Value Euro	*No*	*Value Euro*		No.	Value Euro	
11.04.2019	2.512	423.635.360	985	162.489.275	39	877	145.575.603	*224*	*28.987.957*	*20*	32	4.647.008	4
12.04.2018	2.520	424.719.388	965	158.937.225	38	693	115.798.205	*118*	*14.932.535*	*13*	18	2.477.138	3
13.04.2017	1.694	281.044.143	639	105.351.787	38	191	28.405.025	*17*	*2.123.447*	*7*	9	1.212.810	5
14.04.2016	502	76.071.515	44	6.544.977	9	0	0	0	0				

Source: Own calculations after Archives of Projects Submission Session under the NRDP sub-measures 2014-2020, www.afir.info

After analysing the situation of the projects submitted, selected contracted, finalized but also cancelled during the period 11.04.2016-11.04.2019 (Table 2), it is found that for the above mentioned period only 39% of the total submitted projects were selected for financing, namely 985 projects, of which 877 projects were contracted. Of the total of the contracted projects, only 20% were finalized, a percentage that may seem small, most of the delays in their implementation being often the result of the lack of investment financing, but also delays caused by the evolution of online procurement procedures, especially where there are execution of works contracts. It is noticed that during the analysed period, 32 financing contracts were cancelled, and the largest number, namely 14 contracts, were cancelled in the last 12 months analysed.

One of the eligible actions requested for financing within the analysed Sub-measure is the request for funds for investments in agro-tourism boarding houses or leisure tourism activities. It is thus observed that from the selection reports related to sub-measure 6.4, the sub-measure analysed in the present paper, from all the selected projects, 32.84% have as activity either the establishment of agro-tourism boarding houses, or their modernization and leisure activities in tourism. Besides the projects of this type, the activities financed within the sub-measure are meant to transform the rural into a small urban, precisely to answer the needs that the citizens have (sewing, laundry, car services, dental medical offices, purchasing ambulances, veterinary offices, hairdressers, textile manufacture, clothing, etc.) in order to ensure the continuity of life in rural areas.

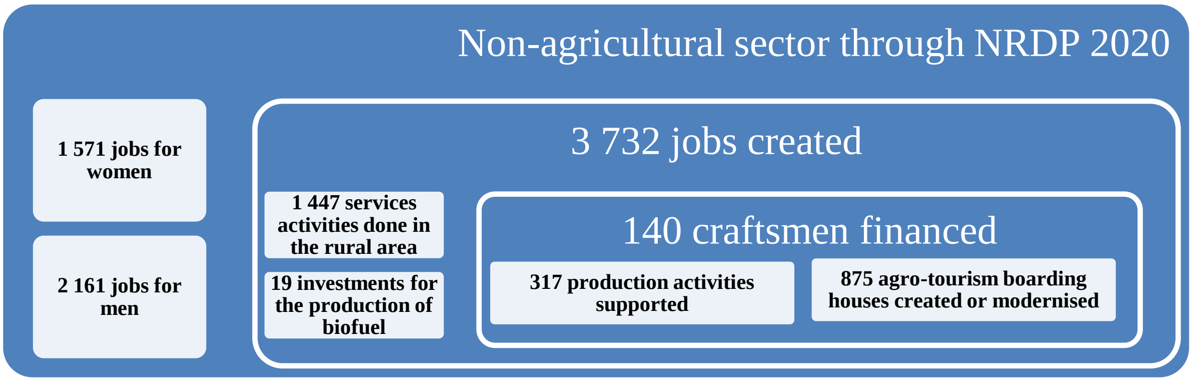

Figure 1. Non-agricultural sector trough NRDP 2020
Source: Own adaptation after AFIR 2018

The above Figure shows in a nutshell the main advantages of NRDP as regards the non-agricultural sector, mostly the creation of jobs and services in an area often lacking of these types of opportunities. The main advantages are those related to the need to keep the youth in and attract others to the rural areas. By creating all the infrastructure of the small urban centres into the rural areas and providing jobs we can reverse the depopulation process that affects most of the rural Romania.

Conclusions

Why does it matter to have a continuation of this type of financing? First of all, this type of financing serves what can be called a "political and legal" purpose as it helps to realise a more cohesive Europe, a social market economy as inscribed in the Treaties that generated a more cohesive Union, by eliminating the social and economic discrepancies.

Secondly, these activities create jobs in areas where the opportunities lack and help improve the local services infrastructures by adding new facilities for the residents of these rural areas. Thus we stop the depopulation process of the rural areas, we retain the youth and on the medium and long term we can hope to have a reverse trend – people coming to those areas from more crowded and expanding urban areas.

Having it maintain in the new CAP is a priority of many Central and Eastern European Members States, Romania included, as the above mentioned advantages and trends are what the EU needs in reducing the West and East discrepancies and rebalancing the continent from the socio-economic point of view, in a time when the global competitions is becoming more and more intense and affects us all.

COW MILK ROUTE FROM ROMANIAN DAIRY FARMS TO MARKET

Irina - Adriana CHIURCIU*, Elena SOARE

University of Agricultural Sciences and Veterinary Medicine Bucharest, 59 Marasti, District 1, 011464, Bucharest, Romania
*Corresponding author: irina.chiurciu@yahoo.ro

Abstract

Milk is obtained in all countries of the European Union and occupies an important place in the economy of the Member States. In Romania the raising of dairy cows is a tradition among the inhabitants of rural and mountain areas. In this regard, the paper presents data on the production and marketing of cow milk for human consumption in Romania. The period covered is from 2010 to 2017. The following data were analyzed: the dairy cow herds, the total cow milk production in Romania and the place occupied with this production in the EU countries, the selling price of cow milk, the position occupied by Romania in the top of the main importers and exporters of cow milk worldwide. Following the analysis, it was noted that the dairy cow herds were steadily decreasing for the analyzed period, starting with 2010. The largest amount of cow and buffalo milk was produced in Macroregion One, on individual agricultural holdings, and the smallest quantity in individual agricultural holdings in the Macroregion Three. In 2017, Romania recorded the lowest price, among the EU countries, for 100 liters of raw cow milk, with an actual fat content. As far as exports were concerned, Romania was ranked 29th in the list of exporters of cow milk worldwide and ranked 19th among importers. The information found in this article was taken from specialized websites such as Eurostat, NIS, Faostat and ITC.

Keywords: *Cow milk, Dairy farms, Milk production, Romania.*

Introduction

Following the studies, it was concluded that approximately 85% of the milk produced worldwide comes from cows and the other 15% from goats, sheep, buffalos, camels, horses, and donkeys (Sawe, 2018).

The European Union is a very important player on the global dairy market, being the main exporter of many dairy products, especially cheese. Milk is produced in each member state of the European Union and represents 15% of the value of agricultural production, being the 2nd product in value.

Given the importance in the nutrition of people, taking into account the role it plays in the economy of the member states of the European Union, the market for milk and dairy products has been and will be one of the markets on which numerous regulations and measures are being acted upon, so that it becomes globally competitive.

The development of the world and European milk products market, as well as the modification of the consumers' options in the conditions of socio-economic expansion and the variation of the production due to the introduction of new technologies, will increasingly influence the sector of milk production and processing which is supported with the help of policy instruments (Giurcă *et al*., 2019).

Romania, even though it already holds the position of member state of the European Union, is facing important problems, which concern both the organization of farms in general and problems related to processing. Producers, processors and traders in this sector must comply with the European Union milk quality standards.

The Romanian milk market has come out over time with various problems, from the onset of mad cow disease, to the growth of cheap imports from countries outside the European Union (Florea *et al*., 2014).
The Romanian consumer milk market is about 1.5 billion liters. It offers three major product types: ultra-pasteurized milk (UHT); pasteurized milk, which together with the extra-pasteurized milk, totals about 10% of the quantity of consumer milk sold in Romania; unprocessed industrial milk, risky for the health of the consumer, but traditionally preferred and which still has a huge share (90%) of the milk sold in Romania.
The last product has an important share in the subsistence trade of the individual producers.
In this general context, the article will present the situation registered on the Romanian milk market, analyzing the official data on the production of cow's milk, the annual average price for fresh milk sold on the agri-food markets, the use of cow's milk and the situation of exports and imports of milk and cream between 2010-2017.

Material and Methods

The data used in this article was found at the National Institute of Statistics (NIS) and other internationally specialized sites. Various data has been consulted. The main tendencies in the production and commercialization of cow milk in Romania have been highlighted with the help of important indicators, such as: the number of cows in Romania and by development regions; total milk production achieved; average price for one liter of milk; annual milk and dairy products consumption per capita; imports and exports of milk. The main indicators analyzed in this paper were studied in their dynamics between 2010-2017. The results presented in the paper were shown in tables, interpreted and illustrated graphically.

Results and Discussion

The growth of milk cattle in Romania has become an increasingly profitable business for the producers who sell their milk at the farm gate with prices between 1-1,40 lei / l, depending on the quantity, quality and the distance to the processor factory that buys it.
From the processing plant to the shelf the price increases almost 5 times, the price difference includes: analysis, processing, packaging, payment of taxes plus the addition of supermarkets for the services of selling a liter of milk.
The price of milk is influenced by processors with 25-30%, the rest is influenced by what happens in the supermarkets.
The price of milk fell for various reasons: the decreased of raw materials and VAT, milk quotas were abolished and the offer increased by 35% due to the Russian embargo, as a consequence of the reorientation of European Union producers to the Romanian market.
Small and medium-sized producers will have to adapt on the go to the conditions of a liberalized market, where increasing imports generate a high level of competition.
Elimination of milk quotas means, for many of the Romanian farmers (small and medium-sized ones) that they face a competition they cannot face. There is the prospect of prolonging the situation in the long term due to the fact that, at European level, the offer of milk is greater than the demand. In this context, large processors have begun to give up contracts with local farmers, preferring to bring raw materials from outside.
Figure 1 shows the dynamics of dairy herds in 2010-2017. According to NIS, the highest value was registered in 2010, of 1,431,406 cows for milk, and the lowest in 2017 - 1,160,136.
While the number of cattle decreased, the number of sheep and goats increased. This was due to the high price of inputs and the low price of milk at the farm gate (Popescu, 2017).

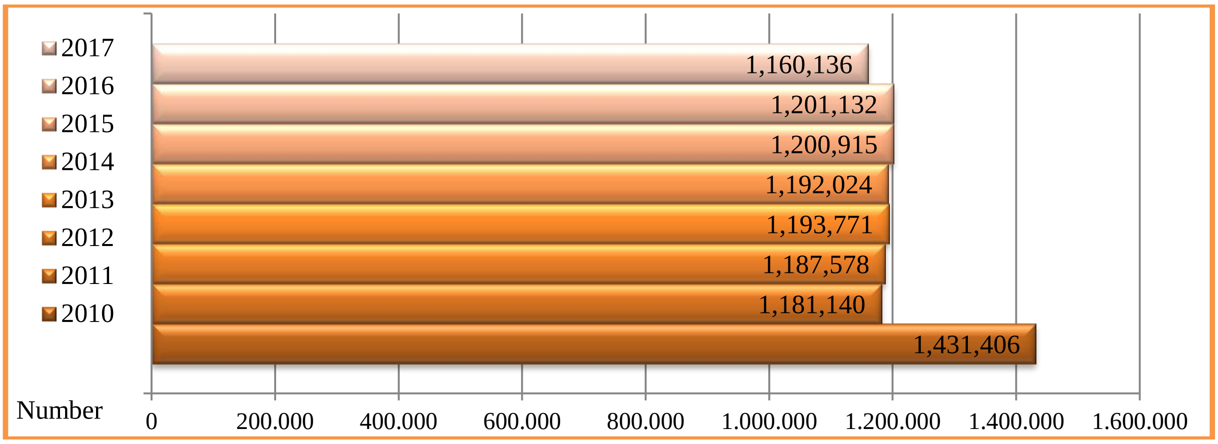

Fig 1 Herds of milk cows (number)

Source: NIS

Due to the number of heads registered in 2017, Romania ranked the 7th among the top dairy farmers in the European Union, where the first places are occupied by Germany, France and Poland (Eurostat)

At the level of macro-regions of development, for 2017 the situation is as follows: the highest number of dairy cows is registered in Macroregion One - 414,999 heads - and the smallest in Macroregion Three, 143,728 heads (NIS, Report Livestock and animal production in 2017).

It should be specified that Macroregion Three was in the last position because here is the Bucharest-Ilfov Region, where the share of land on which agricultural activities are carried out is very small.

Figure 2 provides data on the dynamics of milk production, between 2010-2017. It is observed that the production varies, the largest quantity of milk being obtained in 2014 - 44,015 thousand hl, and the smallest in 2017 - 40,385 thousand hl. With the production obtained in 2017 Romania was on the 13th place in the European Union (Faostat).

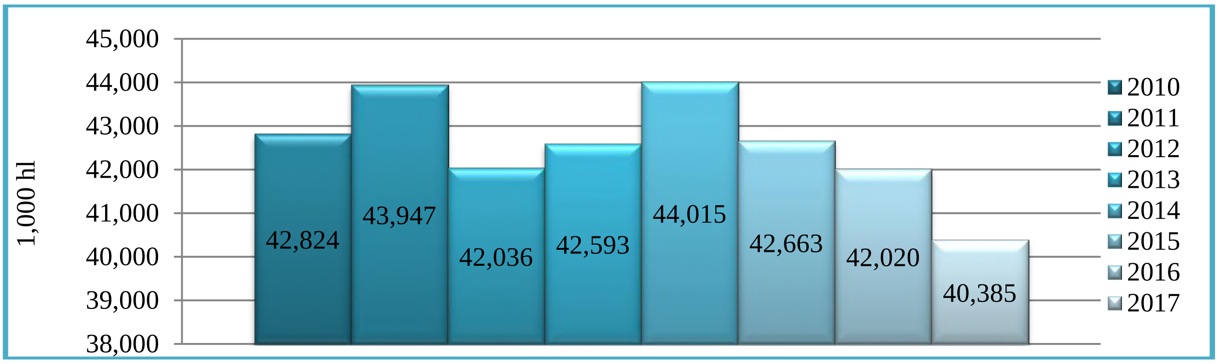

Fig. 2 Production of cow milk during 2010-2017 (1,000 hl)

Source: NIS

At the country level, the largest quantity of cow milk was produced in Macroregion One, 14,703 thousand hl, in the individual agricultural holdings, and the smallest in the individual agricultural holdings in the Macroregion Three, 4,968 thousand hl.

The production of cow milk decreased in 2017 by 3.4% compared to 2016. The development macro-regions registered decreases, except for Macroregion One (Center Region +2.1% and North-West +1%).

The counties that were the leaders in the production of cow milk in 2017 are those in the North of the country: Maramures - Macroregion One, Suceava and Botosani - Macroregion Two (NIS - Report Livestock and animal production in 2017).

Due to the lack of raw milk, processors were forced to buy raw milk from other countries (Popescu, 2017).
Table 1. shows the use of cow milk collected in 2017. As it can be seen, the largest quantity was destined to obtain cheese (13,680 thousand hl).

Table 1 Usage of cow milk - 2017

Specification		Quantity (mii hl)
Production of cow milk – total		40,385
Direct sucked milk		3,514
Milked milk		36,871
of which:	Milk for consumption	10,830
	Milk for butter and cream	1,482
	Milk for cheese	13,680
	Milk for yogurt	211
	Total other products	162
	Animal feed	482
	Delivered to the milk shop	9,990
	Differences and losses	34

Source: NIS, Report Livestock and animal production in 2017

According to the Eurostat Report on the European milk market, as of June 30, 2019, the Romanian milk sector ranked the 2nd, in milk-raw material deliveries to processors, registering an increase of 4.2% compared to June 30, 2018 (Demeter, 2019).

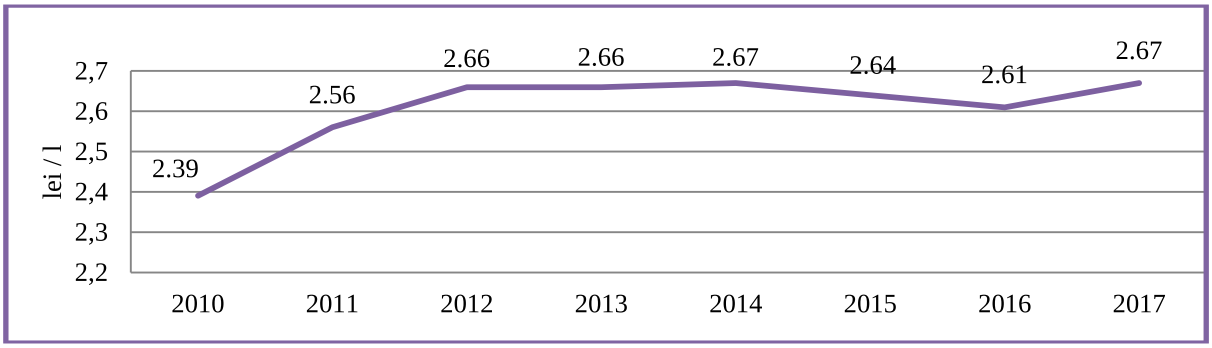

Fig 3 Average annual prices of fresh cow milk, sold in the agri-food markets
Source: NIS

While at the farm gate a liter of fresh cow milk was sold with values between 1-1.4 lei / l, in the agri-food markets it exceeded 2 lei during the analyzed period, as shown in Figure 3.
In 2017 the highest price was registered, of 2.67 lei / l, and in 2010, one liter of milk had the lowest price, of 2.39 lei / l.
The influence of milk prices on profitability is very important. To evaluate the profitability in dairy farms have to be considered both the input cost and the milk output as well as the milk market price (Popescu, 2014).
According to Eurostat, in 2017, the Austrians paid the most, for a liter of milk, 35.8 eurocents/ l and Romania with 28.8 eurocents / l was in the middle of the ranking.
Regarding the consumption of milk and milk products, Romania is not in a leading place in this category. In contrast to the large consuming countries, in 2017, in Romania there was an annual average consumption of milk and milk products, in milk equivalent of 3.5% fat, of 251.4 kg / per inhabitant (NIS). Table 2 presents the main exporters of milk and cream worldwide. Romania ranked the 29th, with a milk export value of 32,543 thousand USD.

Table 2. Exporters of milk and cream worldwide, thousand USD

Specification	Exporters	2014	2015	2016	**2017**	**2017/2014 %**
	World	9,738,031	7,490,713	7,622,325	9,429,135	96.83

Source: ITC, own calculation

Analyzing the data in the table, it is observed that the value exports increased by 22.96%, in 2017, compared to 2014.
The quantitative exports of milk and cream amounted 59,962 tons in 2017, with 59.91% more than in 2014, when 37,497 tons were exported (ITC).
The largest importers of milk and cream worldwide were Germany, Belgium and China (Table 3). Romania ranked the 19^{th}, with an import value of 110,027 thousand USD in 2017.

Table 3. Importers of milk and cream worldwide, thousand USD

19.	Romania	72,891	67,114	82,956	110,027	150.95

Source: ITC, own calculation

The value imports increased by 50.95% in 2017 compared to 2014.
The quantitative imports represented 208,145 tons in 2017, with 74.8% more than the quantity imported in 2014 (ITC).
The production value recorded fluctuations from year to year in the period 2010-2016. In 2016 was registered the lowest value - 1,977.751231 million US $, due to the decreasing of production. Production value has decreased by 19.53% in comparison with 2010, when the value was 2,457.855043 million US $ (Faostat).

Conclusions

The conclusions that can be drawn from this analysis are the following:
- The highest number of milk cows, 414,999 heads, is found in Macroregion One. A decrease of this indicator is remarked in the period 2010-2017;

- Cow milk production varied annually, the most significant production being recorded in 2014 (44,015 thousand hl) and the lowest in 2017 (40,385 thousand hl);
- The annual average consumption of cow milk and dairy products per capita in Romania, in 2017, was 251.4 kg/capita;
- Regarding Romania's quantitative exports and imports of cow milk, an increase during the analyzed period was noticed. Exports increased by 59.91% in 2017 compared to 2014, and quantitative imports by 50.95% in 2017 compared to 2014.

From the data concerning the imports and exports of Romanian cow milk for the period 2014-2017 it can be seen that the imports are ahead of the exports. This has a negative impact on the results obtained both at farm level and at macroeconomic level.

Abstract

Livelihood diversification reduces farm household vulnerability to the adverse effect of climate change. This study aims to analyze livelihood diversification of the farm households in southeast Tunisia. The research used a multistage random sampling technique to collect data from 50 farm households. Data were gathered through structured questionnaires and were described by means of descriptive statistics. The Simpson diversity index (SDI) was used to assess the level of livelihood diversification of households. Furthermore, with reference to the sustainable livelihood framework, the study showed the difference of capital endowments between livelihood groups. It also highlighted the determinants of livelihood diversification using a logistic regression model. The results showed that households with high levels of SDI (SDI > 0.5) were likely to have more sources of income. Furthermore, there was a significant difference ($p < 0.05$) in capital endowments between households that diversified their livelihoods and those that did not. Households with high SDI are more endowed with human, social and financial capital. Results of the logistic model highlighted that level of education, farm size, herd size, non-farm income and distance to the main plot are the key determinants of livelihood diversification.

Keywords:*Livelihood diversification, households, Simpson index, Sustainable livelihood Framework, Logistic regression.*

Introduction

Uncertainties and risks induced by climate change effects have been increased especially in the agricultural sector. Therefore, enhancing the adaptive capacity and the resilience of farm households are needed to deal with these threats. Diversification of livelihood strategies is a key solution to reduce the adverse impacts of climate change (Saha and Bahal, 2015). The concept of livelihood strategies is generally recognized as the combination of choices and activities performed by households in order to attain their livelihood goals (Khatun and Roy, 2012). It includes farm activities as well as non-farm activities. Previous studies showed that the impact of risk in agriculture and the pressure on households' farm income has stimulated the search of alternate revenue sources. Further, it has been reported that in low-income countries, farming activities hardly grant sufficient incomes that meet the needs of households (Fabusoro et al., 2010). Due to this fact, most farm households depend on a diversified portfolio of income sources to spread risks and to stabilize their revenues (Ellis, 1999).
To understand the factors affecting the livelihood strategies, several scholars have used the Sustainable Livelihood Approach (SLA), which was developed by the UK Department for International Development (DFID) (Chambers, 1987; Carney, 2003; Samsudin and Kamaruddin, 2013). The SLA takes into account a complex range of assets on which households depend for their livelihoods (Karl, 2002). This range includes tangible assets (money, land, agricultural equipment) and intangible assets (skills, social networks) (Xu et al., 2015). There are different ways to conceptualize these assets, but the most common is in the form of a pentagon representing five types of capitals: human, financial, physical, social and

natural capital (Carney, 2003). The SLA forms the conceptual and methodological basis for the "livelihoods" analysis that will be carried out in this paper.

Several international studies have been conducted to analyze the households' livelihood diversification (Fabusoro et al., 2010; Saha and Bahal, 2015; Ahmed et al., 2018; Gecho, 2017). For instance, Babatunde and Qaim, 2009 have assessed the households' livelihoods diversification in rural Nigeria. They employed the Herfindhal index to assess the livelihood diversification and the Tobit model to identify the determinants of diversification. They found that the male gender, the education, the productive assets, the pipe borne water and the access to credit are the major drivers of livelihood diversification. Likewise, another study conducted in West Bengal has analyzed the determinants of livelihood diversification. It showed that the educational level, the household experience, the training, the access to credit, the social status and the agro-climatic condition are the major factors affecting the livelihoods diversification (Khatun and Roy, 2012).

However, in Tunisia, there is a current lack of studies investigating the households' livelihoods diversification. This research tries to fill this gap through a case study of households from Medenine province, which belongs to South-East Tunisia. The purpose of this paper is to assess the level of diversification of these farm households and to analyze its main determinants.

Materials and Methods

The study was carried out in the Oum Zessar watershed, which is located in the northwest of Medenine province. It covers an area of 350 Km^2. It is spread over a territory of 11 imadas belonging to three districts: Beni khedache, North Medenine and Sidi Makhlouf. A multistage random sampling technique was employed. In the first stage, the three districts were selected to cover the entire watershed. In the second stage, out of the 11 imadas of the watershed, nine were selected randomly. In the third stage, households were selected randomly from each imada. Overall, 50 farm households were selected for this study. Data were gathered using a survey questionnaire with farm households.

To evaluate the level of households' livelihood diversification, this research used the Simpson Diversity Index (SDI), which was established by Edward H. Simpson in 1949 (Ahmed et *al.*, 2018). The SDI calculates both the number of livelihoods practiced by a household and the proportional contribution of each livelihood. We considered three types of livelihood strategies: crop-oriented, livestock oriented and off-farm-oriented. The SDI is calculated using the following equation:

$$\mathbf{SDI = 1 - \sum_{i=1}^{N} P_i^2} \qquad (1)$$

Where : N represents the number of income sources and P_i is the income proportion of the i-th income source. The value of the SDI is between 0 and 1. Households with less diversified livelihoods are associated with the littlest values of SDI. Those with a highly diversified income have a high SDI value. The SDI was calculated for each household and was used to group sample households into two groups according to their level of diversification. The level of livelihood diversification was interpreted using the SDI values: if SDI < 0.5, the household's livelihoods are lowly diversified; if SDI > 0.5 the household's livelihoods are highly diversified. Then, using the Sustainable Livelihood Approach (SLA), we compared the capital endowment between the two households' groups. Indicators used to quantify each capital (Table 1) were selected based on a literature review and on the availability of data in our database. Overall 17 indicators were chosen to apply the SLA framework. It was crucial to standardize each indicator because of the heterogeneity of units obtained from the raw data, the following formula was used:

$$\mathbf{Index\ I_h = (I_h - I_{min}) / (I_{max} - I_{min})} \qquad (2)$$

Where I_h is the original variable of household h, I_{min} and I_{max} are respectively the lowest and highest value of variable among all households.
In this paper, the decision to highly diversify livelihoods by households or not is considered a dichotomous variable, hence the use of a logistic regression model (McFadden, 1973).
For this dichotomous model, a logistic regression analysis using maximum likelihood was performed to test the effect of several explanatory factors on the probability of "livelihood diversification by households". If multicollinearity problem exists in the model, it is difficult to determine the effects of the explanatory variables on the dependent variable. Therefore, the multicollinearity problem between explanatory variables was tested before running the logistic model. Once we find two correlated variables, one of them should be eliminated to solve this problem (Ahmed et al., 2018). Finally, as shown in eqation (3), seven variables were maintained to run the logistic model. The obtained model is as below:

$$\textbf{LDI} = \beta_0 + \beta_1\ \textbf{Education} + \beta_2\ \textbf{Farm size} + \beta_3\ \textbf{Herd size} + \beta_4\ \textbf{Distance to the main plot} + \beta_5\ \textbf{Experience in agriculture} + \beta_6\ \textbf{Non-farm-income} + \beta_7\ \textbf{Distance to the market} + \mu_i \quad (3)$$

Where, LDI: Livelihood diversification index, β_0 = Intercept, μ_i = Error term

Results and Discussion

Study's results showed that all households are diversifying their livelihoods, while, the level of diversification differs among households. The average value of SDI for the whole sample was 0.41 with a standard deviation equal to 0.45. This indicates a great variability in the levels of diversification between households. This led us to classify the households into two groups using the binary logistic regression (0 for households with low level of diversification and 1 otherwise).

Table 1. Difference in capital endowment between the two groups of households

Livelihood Capital	Indicators	Group 1 (SDI<0.5)	Group 2 (SDI>0.5)
Human capital	Age	0.700	0.333
	Household size	0.448	0,614
	Dependency ratio	0.185	0.273
	Number of years of education of head of household	0.434	0.698
	Trainings	0.306	0.607
	Number of years of experience in agriculture	0.534	0.221
Physical capital	Value of agricultural equipment	0.308	0.002
	distance from the main plot	0.010	0.179
	Herd size	0.320	0.160
Natural capital	Farm size	0.308	0.154
	Irrigated area	0.149	0.002
	Number of olive tree	0.100	0.274
	Crop diversity index	0.412	0.189
Social capital	Membership in any organization	0.136	0.536
	Distance to the market	0.130	0.427
Financial Capital	Non-farm income	0.339	0.658
	Subsidies	0.089	0.000

Group 1 encompass 54% of the surveyed households that have a low level of diversification (SDI<0.5). Nevertheless, the other 46% have high SDI values. Table 1 and figure 1 compares the capital endowment between the two groups. There was a difference in the amount of livelihood capital between the two groups. Group 1 possess more abundant physical (0.212) and natural capital (0.242). Group 2 owns more abundant human (0.457), financial (0.328) and social capital (0.48). These differences were statistically significant (Figure 1).

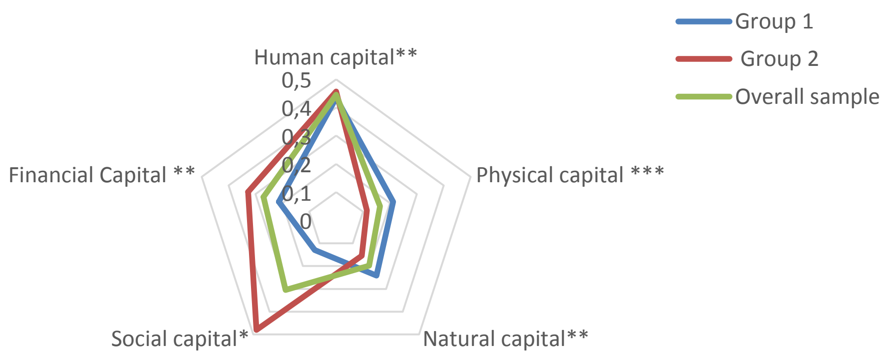

Figure 1. Difference in capital endowment between the two groups of households (*1% significance, ** 5 % significance, *** 10% significance)

Table 2 presents the results of the logit model estimation (Y) which explains the probability that a household will highly diversify its livelihoods. The model is statistically valid. Indeed, the validity of the estimated model is analyzed through the Wald $\chi^2(5) = 10.48$ statistic, which tests the equality to zero of all the model coefficients. On the other hand, he showed that the coefficients retained in the model were significantly different from zero at the 5 % threshold. Consequently, the hypothesis of nullity of the coefficients is rejected. The Wald χ^2 tested also the link between each of explanatory variables and the household's livelihoods diversification.

Using R^2 McFadden, good adequacy of the models was demonstrated. In fact, R2 has a satisfactory high value R2 =0.66, which prove the model performance.

Table 2. Predictability of the Logit model

Logit (LDI)	Coefficients	Pr > Chi²
Education	2.999	0.005*
Distance to the main plot	0.968	0.038**
Experience in agriculture	-0.521	0.205
Farm size	-2.364	0.014**
Herd size	1.126	0.089***
Distance to the market	0.756	0.182
Non-farm-income	0.928	0.092***
Wald χ^2	10.481	
R^2(McFadden)	0.662	
AIC	69.41	

*1% significance, ** 5 % significance, *** 10% significance

Then, we tested the independence of the explanatory variables with each other (Table 3). This led to a reduction in the number of variables and allowed us to avoid multi-collinearity. To test the existence of multi-collinearity, the explanatory variables were verified using a

variance inflation factor (VIF) which makes it possible to detect the multi-collinearity of the explanatory variables (Asfaw et al., 2017).
In our model, there is no multi-collinearity between the variables (Table 3). In fact, a variance inflation factor (VIF) and its inverse (1 / VIF) are used to verify the explanatory variables.
(1 / VIF) is greater than 0.1. Therefore, it can be concluded that the model variables explain significantly the household's livelihoods diversification.
Results analysis of the Logit econometric model (Y) presented in Table 2 shows that the significant variables were: level of education (1% threshold); land size and the distance to the main plot (5% threshold) and herd size and the non-farm income (10% threshold).

Table 3. Variance Inflation Factor (VIF)

Variables	VIF	1/VIF
Education	3,666	0,27275655
Distance to the main plot	1,281	0,78047636
Experience in agriculture	1,802	0,55486122
Land size	1,552	0,6441241
Herd size	1,190	0,84043628
Distance to the market	1,891	0,52881396
Non-farm-income	1,677	0,59629127

Logistic regression results indicate that the education variable is significant at the 1% level and positively correlated with the livelihood diversification (C = 2.999, Pr > χ^2 = 0.005). This suggests that a household head with a high level of education is more likely to diversify its livelihood. The high educational level of the household heads makes them able to look for employment activities and to undertake highly remunerative activities. This result is in line with previous researches, which found that the education is essential as it offers abilities and skills that enable households to secure well-paying jobs (Adebayo et al., 2012; Chaplin et al., 2002; Fabusoro et al., 2010). Thus, the vulnerability of their livelihoods may be reduced.
The findings from the logistic regression show that the farm size is significant at 5% threshold but with a negative sign (C =-2.364; Pr > χ^2= 0.014). This indicates that households with small farm size are more likely to diversify their livelihood strategies. The inverse relationship between the farm size and livelihood diversification have been revealed in several previous studies (Fabusoro et al., 2010; Adebayo et al., 2012; Sallawu et al., 2016). This affirmed that when agricultural activities offer sufficient revenue, households tend to decrease the diversification of their livelihood strategies. Indeed, households with large farm size are more likely to involve in agricultural activities as it requires more labor and enables them to ensure food security. Further, results in table 2 reported a positive coefficient of herd size, which was significant at 10% threshold. This indicates that the herd size was a determinant of household's livelihood diversification. Comparison of this finding with those of other studies confirms that the livestock endowment appears to be a crucial asset for improving diversification (Eneyew, 2012, Saha et al., 2015). A possible explanation for this might be that livestock help to generate more income and reduce liquidity constraints through selling animals. Moreover, the findings of this research suggest a significant (at 10% level) and a positive relationship of the non-farm income with livelihood diversification. The non-farm income is a source of investment for farm activities particularly in case of financial problem. It can further support the household's livelihood diversification and raise their standard of living. Finally, our model showed a positive and significant effect of the variable "distance to

the main plot". We can conclude that the proximity to the main plot is one of the factors that facilitate the management of the farm.

Conclusion

The study analyzed the livelihood diversification of farm households in the province of Medenine-Tunisia. The diversification seems to be a common practice. It was infrequent to find a household without non-farm income. However, the level of diversification differs between households which affect their capital asset. It was found that households who highly diversify their livelihoods have more abundant human, social and financial capital. Many determinants either negatively or positively affected the livelihood diversification. On the first hand, the education, the herd size, the non-farm-income and the distance to the main plot have positive and significant effect on livelihood diversification. On the other hand, the farm size and the experience in the agricultural sector have significant but negative effect on livelihood diversification.

AN ANALYSIS OF THE CURRENT SITUATION OF SEED SECTOR IN TURKEY

Nilgün GÜMÜŞAY*

Ministry of Agriculture and Forestry,Department of Training and Publication, International Agricultural Training Center,Turkey
*Corresponding author: nilgungumusay@gmail.com

Abstract
Turkey has optimum climatic conditions, large lands, and geographical location advantage for the production of high-quality seed. In the country, as the public sector has been dominating the seed sector until the 1980s, the private sector has started to operate in the mid-1980s as a result of the legal and administrative regulations made at that time. Thus there has been a significant progress in the sector regarding human resources, capital accumulation and technology transfer with the cooperation of domestic and foreign companies. The Law on the Protection of Breeders' Rights for New Plant Varieties Law No.5042 and Seed Law No. 5553 were entered into effect respectively on 15.1.2004 and 08.11.2006. By Seed Law No. 5553, quality assurance in seed production has been provided; plant variety registration system in accordance with the EU and seed, seedling and sapling certification system have been established. The law has contributed to the development and strengthening of the sector through new regulations on the seed production and trade. In parallel with the developments in the sector, seed production and exports of Turkey have gradually increased over the years. The production amount increased from 145,227 tones in 2002 to 1 059 300 tones in 2018 and seed exports to 85 countries realized as 151,691 million US dollars and an amount of 102,786 thousand tones in 2018. Despite these developments, various problems still exist in the sector such as lots of small capital firms in the sector, lack of qualified technical staff, lack of capital to be allocated to R & D, problems regarding technology transfer, high production cost, the informal production and sale of seed, and the need for legislative amendment on some issues. In this study, the current situation in Turkey on seed sector is examined and basic problems and solutions to them in the sector are discussed.

Keywords: *Seed, Seed sector, Production, Trade*

Introduction
Although seed is the basic and most crucial input for crop production, it has become a product of industrial and economic value today. The use of high quality seeds is of great importance in increasing agricultural productivity and seed has a strategic importance for the agricultural sectors of the countries. With this in mind, developed countries have turned to policies that develop and strengthen the seed sector and have started research and development activities on this topic. As a result of these policies, the seed sector in these countries, which has a history of nearly 150 years, has developed greatly with their strong capital accumulation and advanced technological research opportunities and these countries have played an important role in the world seed trade today (Bağcı, 2011). The private sector-dominated seed sector has only a 30-year history in Turkey. In recent years the sector has improved considerably in terms of production and exports in the country. The production amount increased from 145,227 tones in 2002 to 1 059 300 tones in 2018 and seed exports to 85 countries realized as 151,691 million US dollars and an amount of 102,786 thousand tones in 2018.
Agricultural land in Turkey is around 38 million hectares, of which 23 million hectares consist of arable land and 14 million hectares of grassland and pasture land. The share of field crops in the arable areas is 39%, fruits 9%, vegetables 2% and fallow land 10%.

Furthermore, there are two Seed Gene Banks in the country. These are the National Seed Gene Bank of İzmir and the Seed Gene Bank of Turkey in Ankara. These institutions perform the collection, conservation and documentation of the plant genetic resources and make the other studies related to the seeds. As of 2015, 120,995 materials of 3,244 species have been preserved in the seed gene banks.
The main objective of this study is to examine the current situation of seed sector and discuss the basic problems and solutions to them.

Material and Methods

This study is based on the research of theoretical review and secondary data obtained from Turkish Statistical Institute (TÜİK), Ministry of Agriculture and Forestry (MoAF), Ministry of Trade (MoT), Sub-Union of Seed Industrialists and Producers (TSÜAB). The legal documents, articles, reports, websites and journals were employed to identfy the present situation of the seed sector and the basic problems and solutions to them in the sector.

Seed Sector in Turkey

Turkey has a big potential for seed production due to its favorable geographical condition and climate. The seed sector, which had a public dominated and monopolistic structure until the 1980s, has shown significant developments after these years as a result of substantial structural reforms and the transition to a free market economy (Elçi, 2000). With the liberalization of the economy and the abolition of restrictions on seed foreign trade, many domestic and foreign seed companies entered the sector either directly or through partnerships and seed sector has became a private sector dominated structure with the increase of the number and capacity of these companies in the sector.
Reviewing the sectoral structure of the seed industry, organizations operating in field crops and vegetable seed production and breeding can be grouped into four main headings. These are as follows:

1. Public Agricultural Research Institutions under the Ministry of Agriculture and Forestry and Universities
2. General Directorate of Agricultural Enterprises (GDAE) under MoAF
3. Unions and Cooperatives
4. Private Sector Seed Companies

Currently 26 public institutions, many union and cooperatives and 907 companies in various sizes which has either domestic or foreign capital exist in seed sector.

Legal Framework of Seed Sector in Turkey

Ministry of Agriculture and Forestry is responsible for both regulating and controlling the seed sector in Turkey and seed legislation and regulations of Turkey are largely in accordance with the ones of EU countries. The Seed Law No. 5553, which has come into effect since 1963, was amended by the parliament in 2006. By this law, quality assurance in seed production has been provided; plant variety registration system which is in accordance with the EU's and seed, seedling and sapling certification system have been established. Furthermore, some provisions has been added to the law for the establishment of professional organizations such as unions and sub-unions and upon its entry into force one union and 7 sub-union have been established in 2008.
The establishment of these unions and sub-unions has ensured the integrity of the sector. All seed industry and producers operating in Turkey must be a member of Sub-Union of Seed Industrialists and Producers. As of June 2019, the number of the members of TSÜAB is 907 (Sub-Union of Seed Industrialists and Producers, 2019).

Member companies of TSÜAB are engaged in activities such as plant breeding and variety development, protecting of varieties, cultivation, processing, packaging, marketing and distribution of original, basic and certified seeds, and export and import of seeds. Each stage of seed production is carried out in accordance with international rules in Turkey.
Additionally, Turkey's UPOV membership was approved by the national assembly and Turkey became an UPOV member in 2007.

Seed Production in Turkey

Seed production in Turkey is carried out by both public and private sectors. Wheat, potato, barley, corn, cotton and sunflower seeds are the leading products in certified seed production. Within seed supply system, Public Seed Agencies are currently engaged in a limited production and distribution activity focusing on self-pollinated plants such as wheat, barley and some forage crops. However, in recent years, private seed companies have also started to increase their market share significantly in these species (Table 1).

Table 1- Seed production inTurkey (tones)

Year	*Total Production (Public Sector +Private Sector)*	*Wheat*	*Barley*	*Soybean*	*Corn*	*Sunflower*	*Potato*	*Cotton*	*Vegetable*	*Forage Crope*
2003	Total Production	**100 101**	**11 194**	**343**	**21 399**	**5 628**	**25 395**	**7 662**	**992**	**2 600**

	Share of Private sector %	60	85	100	100	100	100	100	100	79

Source: MoAF

Turkish seed sector has grown rapidly since the new Seed law came into force in 2006. Government policies supporting certified seed usage and domestic certicfied seed production has resulted in the rise of the production capacity of both the government and private sectors. Certified seed production has increased about three fold in last ten years, with a total production of 1 059 300 tones in 2018. Likewise, while the share of private sector in total production was 40% in 2003, this rate rose up to about 80,16 % in 2018. The private sector has produced all hybrid corn, hybrid sunflower, cotton, potato, soya, vegetable seed productions in Turkey since 2016 (Ministry of Agriculture and Forestry, 2019).

At present, an important part of certified seed production for wheat, barley, rice, and some forage crops and pulse seeds is made by using the varieties which have been bred in Turkey (Karahan, 2017).

Seed Trade

Turkish seed sector; both in terms of legislation, infrastructure and ecological opportunities, and with its cooperation and membership with international organizations, has an important advantage in domestic and international markets (Karahan, 2017).

The permission of the Ministry of Agriculture and Forestry is required for seed import and export in Turkey and the imported seed must comform with domestic requirements. The companies which are registered with the Turkish government as seed producers can get permission for seed import and import is allowed for certified seeds of registered varieties in Turkey.

Turkey seed market is mainly based on three categories, that is:cool climate grains, forage plants and industrial plants and vegetables. The largest share in the market belongs to hybrid vegetable seeds. Industrial plants consisting of hybrid seeds such as corn, sunflower, cotton and sugar beet are in the second place. The third group, particularly including certified wheat and barley seeds, ranks third in value but first in quantity (Ministry of Trade, 2016). Products which have the highest export rate in terms of volume in Turkey, are respectively, wheat, sunflower, corn, potato, barley, cotton and forage crops. Products which have the highest import rate in term of volume are potato, forage crops, knotgrass, corn and vegetable seeds (Ministry of Agriculture and Forestry, 2019).

Looking at the seed export data of Turkey, the export has been on the rise in recent years. While Turkey's seed export in 2012 was approximately 121 million dollars, this figure increased to approximately $ 152 million in 2018 with an increase of 25% in value basis.

On the other hand, the value of import has decreased from 197, 6 million dollars in 2012 to 178,8 million dollars with a decline of 9% in value basis in 2018. The ratio of exports to imports increased from 61 in 2012 to 84,8 % in 2018.

Tablo 2-Seed foreign trade figures

	2012	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**
Export (Million dollars)	120.7	126.0	148.3	102.7	153.4	137	151.7
Import (Million dollars)	197.6	194.2	188.4	202.1	202.1	189	178.8
The ratio of exports to imports (%)	61	65	79	51	76	72,5	84,8

Source: MoAF

While Turkey exported seeds totally 76 different countries in 2016, this number increased to 85 countries in 2018. The number of export countries rising year by year. In 2018 Russia ranks first in export with the percentage of 12, 9%, then Ukraine and Iraq come second and third with the percentages of 12, 1% and 11,9% respectively in value basis. On the other hand, France, Italy and Netherland were the top three importers with the import share of 15.4%, 11.0% and 8.8 % respectively.

Seed Supports in Turkey

The government has given subsidies to the farmers for domestically produced certified seed usage in order to promote the use of certified seed since 2005. Likewise, seed producers producing certified seed in Turkey have been supported by the government since 2008. Support prices for domestic certified seed usage are shown in the Table 3.

Table 3-Subsidiy amount for farmers using domestic certified seed in 2018

Support for domesticall yseed usage (TL/da)	TL/Decare
Safflower canola, sesame	4
Rye, oat	6
Paddy Rice	8
Wheat	8,5
Barley	8,5
Trefoil	20
Clover	30
Chickpea, Bean, Lentil, Soybean	20
Potato	80

Source: MoAF

Seed Law No. 5553 and subsidies have contributed significantly to the development of the sector as well as the increase in certified seed usage and production.

Basic Problems and Solutions

Problems related to seed sector; legislation and legal problems; reseacrh and development (R & D) and technology problems; and high production costs, financing, inspection and marketing problems.

Legislation and Governance Issues:

Regulatory problems are due to the need for new regulations arising from changing conditions and trade patterns of the day, and problems related to existing legislation.

There are many sub-titles under this issue, such as market control, penalties, inspection of seed dealers to prevent unlicensed illegal seed sales, field controls, authority transfers from the public sector to the private sector, disintegration of authority on issues concerning seed sector, packaging and packaging, supports, production, local administrations, seed import and export. In addition, subsidies for certified seed production and use are insufficient and more support is needed by the sector. Likewise, R & D activities are not adequately supported.

Increasing state subsidies will contribute positively to the production, use and export of certified seeds.

Moreover, although the seed sector has extensive production and seed processing lines and factories, the sector cannot be considered as an Agri-Industrial Organization (SME) in Turkey and cannot benefit from the support of many SMEs. Granting these companies SME status will enable them to benefit from many domestic and international market supports (Turkish Seed Industry Association, 2016). The Seed Law No. 5553 provides for the establishment of specialised courts for issues related to seed. However, disputes regarding the seed remain in these courts for a long time and do not result in time.

In addition, more attention should be paid to auditing and the transfer of authority from the public sector to the private sector should be ensured for further development of the sector. (Bağcı and Yılmaz, 2016). Similarly, more emphasis should be paid to more effective cooperation between the public sector, civil society and the private sector in order to solve sector problems effectively in drafting and reviewing legislation.

High Productıon Costs:
The relatively high labor cost, especially high public land leases, expensive production inputs and high royalties paid to foreign companies and public institutions lead to high production costs. It is important that public and private sector representatives should carry out cost studies for determining production costs. Investment costs should also be taken into account when determining the cost per kg. of a product which have been bred (Ministry of Agriculture and Forestry, 2018).

Financing Problem:
Majority (83%) of the companies operating in the sector are composed of medium and small sized companies. Small firms has insufficient financial resources for infrastructure investment and R&D programs. This negatively affects the development of the sector and the volume of exports. In order to overcome this problem, it should be built up new funding and support programs.

R & D and Technology Problems:
Private sector R & D level is inadequate due to lack of qualified R & D personnel, the small size of the company, high laboratory and infrastructure investment costs and the inability of the majority of companies in the sector to afford R & D risks. The need for qualified personnel is one of the biggest problems for all companies of the sector.
One of the main reasons for importing seeds and varieties from abroad is that it is high costs and dependent on foreign agricultural technologies. It is expected that opening the technological and physical infrastructure of MoAF to the private sector, provided that R & D projects are implemented, and increasing R & D supports to the upper limits will contribute to solving the problems of the sector in this field (Ministry of Agriculture and Forestry, 2018). In this way, the competitiveness of the companies which are engaged in vegetable seed breeding and production will be increased in the domestic and foreign seed market.

Conclusions

Turkey has made significant progress in the seed sector in recent years and has completed its integration with the world by becoming a member of international organizations and establishing legal and technical infrastructure. Consequently, for the further development of the seed sector in the country, which is also advantageous in terms of climate and ecological conditions, the farmers should be more encouraged for the use of certified seed, R & D activities should be given more importance and supports for R & D activities should be increased, training of technical experts in the sector should be encouraged, variety breeding activities should be encouraged and policies aimed at improving competitiveness of the sector should be prioritised by taking into account developments both in Turkey and the world.
On the other hand, as a major producer country in terms of vegetables and field crops and with the development of the agricultural industry and greenhouse cultivation, Turkey has significant opportunities at international markets, particularly at Central Asia and Middle East countries, North Africa, Balkans and Eastern European countries
Therefore, a good market analysis in these regions, especially the harmonization of seed legislation and technical cooperation in the Seed Association of Economic Cooperation Countries (ECOSA) should be one of the country's future strategies (Bağcı, 2019).

Abstract

The subject of this paper is the contemporary aspects of sales management in the digital environment. Sales management is a business discipline that focuses on the practical application of sales techniques and the management of a firm's sales operations. The growth of competition, the globalization of the market, the shorter product lifecycle, the increase in indirect competition in all spheres of business have all influenced the new approach to managing the sales process. The main goal of the paper is to analyze the significance and necessity of investment in information and communication technology and modern software solutions in sales management. Contemporary sales are becoming highly dependent on information and communication technologies, both for traditional commerce and especially for e-commerce. Global computer networks have brought tremendous benefits to commerce as well as new problems. Successful sale of agricultural products within a short period of their harvest is essential to the overall growth and survival of agribusiness. Agricultural producers are also trying to develop digital sales channels.

Keywords: *Sales management, Digital environment, Agribusiness*.

Introduction

The simplest way to think of the nature and role of selling, traditionally called salesmanship, is that its function is to make a sale (Jobber and Lancaster, 2015). In the traditional sense, selling encompasses a set of activities and tasks that organizations undertake to deliver goods and services. In economic terms, selling is the final stage of the process of production. Salespeople and sales teams are currently engaged in redefining their roles and adopting new forms of selling. These changes have been brought on by rapid developments in market conditions as well as by growing customer expectations. Sales management essentially boils down to planning, realizing and controlling the programs of personal contacts, designed with the goal of achieving a firm's sales and profit objectives (Jobber and Lancaster, 2015). Sales management is a business discipline which is focused on the practical application of sales techniques and the management of a firm's sales operations.

The trends of sales management give increasing importance to building customer relationships, team sales, sales profitability which requires strategic planning incorporated in selling and marketing programs, leadership due to the complexity of managing the sales personnel and, finally, they adopt a wider global market perspective. In addition, more stress is placed on the strategy of direct communication, which puts the emphasis on the dialogue with and feedback received from the customer that make product improvement possible. The growth of competition, the globalization of the market, the shorter product lifecycle, the increase in indirect competition in all spheres of business have all influenced the new approach to managing the sales process.

The digitalization as a social process refers to the transformation of the techno-economic environment and social-institutional operations via digital communication and applications. Digitalization is the use of digital technologies to change a business model and provide new revenue and value-producing opportunities (Gartner Group, 2019). It is the process of moving

to a digital business. Digitalization strongly influences both agricultural production and the ways in which agricultural products are sold.
The purpose of this paper is to provide an overview of the impact of digital transformation on sales management, in particular on agricultural product sales management and on agribusiness in general.

Material and Methods

The paper is based on an extended review of secondary data from relevant international institutions and the articles and literature of reference authors.
The technological, legal, economic and agribusiness aspects of digitalisation of sales management have been specifically considered.

Results and Discussion

The technological aspects of sales management in the digital environment

One of the most prominent technological trends is the use of IT resources as a service, not a product. This modern approach in IT is called *Cloud Computing*. The definitions of this term abound, but it seems that the definition provided by the *Computer Security Division of the U.S. Department of Commerce* (Mell and Grance, 2011) best captures the concept's essence. It reads: "*Cloud Computing* is a model for enabling convenient, on-demand network access to a shared pool of computing resources, e.g. networks, servers, storage, applications and services, that can be rapidly provisioned and released with minimal management effort or service provider interaction." Over the previous years, the concept of *Cloud Computing* has become more accepted in the marketplace. The *Cloud* model may hold special appeal for small firms that have limited IT personnel.
One of the pressing concerns in the development of the business software industry is how to create software tools for handling vast data volumes, since these have become commonplace in business systems. There is a need to provide storage for this data, but also to enable quick and efficient user access. This is why the concept known as Big Data will continue to gain ever greater significance in the future. This concept is described by *McKinsey Global Institute* using the 4V characteristics (Manyika *et al*., 2011): **V**olume (the enormous volume of data); **V**ariety; **V**elocity (the speed of gathering and turning data into knowledge); **V**alue (creating value based on the gathered data). IBM describes the *Big Data* concept using 3V (**V**olume, **V**elocity, **V**ariety) (Zikopoulos and Eaton, 2012).
The third technological trend that significantly influences changes in sales management is the concept of the IoT. The Internet of things (IoT) is a concept which expands the virtual world and the Internet to real-world physical things, thus enabling resource virtualization.

Economic aspects of sales management in the digital environment

The growth of the global economy and the global computer network enabled electronic commerce as a new segment of modern business. The market established on the World Wide Web provides new commerce possibilities, but requires a change in the approach to the very concept of commerce, which is termed e-Commerce. Communication-wise, e-Commerce comprises the delivery of information, products, services or paying for them via smart phones, computer networks or some other means. Business-wise, e-Commerce represents the application of technology to automate business transactions. Service-wise, e-Commerce is a tool that reduces costs, improves the quality of the goods and decreases delivery time.
E-Commerce provides new sales channels which make possible the interactive relationship between the seller, i.e. the supplier, and the buyer while increasing productivity and reducing costs. The model of networked global business has provided the following benefits to the firms that utilize it: cuts in business costs; customer satisfaction; a decrease in goods delivery

times and a reduction in the number of complaints; improved customer support; savings in distribution, etc. The electronic environment has given rise to software applications for managing the sales chain, which integrate the cycles of sales or orders and make them more efficient by increasing the speed of data exchange between the customer and the seller, which results in increased customer confidence and reduced purchase times. The companies that offer their products and services through a large number of channels require a new generation of e-Commerce applications. As the sales channels evolve, so does the process of selling. The companies face the decision of which new business practice to adopt to limit delays, support direct or self-service sales. E-Commerce enables competitive business and increases the survival rate in the marketplace. To develop e-Commerce, certain technological prerequisites have to be met. First and foremost, an information highway must be available, i.e. the infrastructure of sufficient capacity and an information transport service provider branched out in various communication networks.

Legal and regulatory aspects of sales management in the digital environment

In addition to technological prerequisites it is necessary to provide and improve the legal prerequisites which enable the unhindered development of electronic commerce, copyright and privacy protection and secure universal network access and suitable pricing policy for network access and information usage. All of this contributes to the existing dedication to activities at the national and global levels aimed at harmonizing laws and regulations on electronic commerce, electronic contracts, digital signature, remote payment, etc. The most important international regulations are: the UNCITRAL Model Law on Electronic Commerce; the EU Directive on certain legal aspects of electronic commerce in the Internal Market; the Directive of the European Parliament and of the Council on a Community framework for electronic signatures; the UNCITRAL Model Law on Electronic Signatures; the UNCITRAL Convention on the Use of Electronic Communication in International Contracts.

The EU Directive on the e-signature established a common framework for the development of the law on the e-signature in the EU, and therefore it promotes the legal recognition of the e-signature and its more widespread use. Only an advanced e-signature (supported by a qualified certificate and created with a secure private key) is considered a full legal equivalent to a handwritten signature, but all e-signatures are potentially admissible as evidence in the court of law. The objective of the Directive on e-commerce is to promote e-commerce in the EU. The Directive on e-commerce contains a framework for the member states' laws on e-commerce. In accordance with it, regulations have been recommended that deal with: the providers of certification services; e-contracts; the responsibility of intermediaries and the rules of conduct; dispute resolution and civil procedure. Each member state is responsible for regulating its e-sellers and may not restrict the activities of e-sellers established in another member state. E-sellers have the responsibility to: provide full information in advertisements (professionals must adhere to their professional advertising standards) and must confirm the receipt of the order without delay. The Internet service provider is not held legally responsible for the content of information if they act as a mere conduit, cache or host.

The Committee on Internal Market and Consumer Protection of the European Parliament passed the Digital Content Directive (DCD) that was provisionally agreed upon by the Council of Europe in 2019. The compromise ensures that the DCD conforms to the Directive on the sales of goods in classical commerce and provides a coherent and clear legal framework on digital content commerce. The Directive is intended to ensure a high level of protection and legal security to European consumers, especially when making purchases in other member states, as well as to provide support to the sellers, the small and medium-sized firms in particular, in offering their goods and services in the entirety of the EU market. The

Directive's objective is to harmonize to the greatest extent possible the rules of contracts on the provision of digital content in the whole of the EU, while allowing the member states to retain or introduce provisions in certain regulatory areas, e.g. a longer period of legal guarantee. Member states will also be able to regulate the general aspects of contract law, such as entering into, the validity, futility and termination of contract to the extent that they are not regulated by the Directive, or the right to compensation. Apart from the Digital Content Directive, the Proposal for the directive on the treaty on better implementation and modernization of consumer rights in the EU (the so-called omnibus directive, a part of the legal regulations on the digital commerce and services (e-commerce) in the strategy of the Single digital market) is in its preparatory stage.

Sales management in the digital environment from the aspect of agribusiness

E–agribusiness can be defined as any form of business transaction in which the parties interact electronically rather than by physical exchanges or direct physical contact. Doing agribusiness on-line through internet is generally referred to as electronic agribusiness. In short it is called as "E-agribusiness" (Dash and Mohapatra, 2017).

It is also referred to as application of e-commerce in agribusiness. Basically it is Information Technology (IT) based agribusiness. Therefore, E-agriculture is a promising area encompassing the agricultural value chain through the application of the Internet and related technologies.

Application of E-agriculture encompasses all agriculture and infrastructure projects in which ICT has the potential of enabling the empowerment of the community, such as: Providing Internet Demand Based Agriculture Information through ICTs, helping farmers to access information on commodity prices. Such practices are adopted for crop cultivation and in forging direct relationships with potential buyers in order to provide better value for their produce (Dash and Mohaptra, 2017).

How does the Netherlands, a country significantly smaller than Australia, manage to produce $158 billion in agricultural food exports compared to Australia's $50 billion? Why is agricultural food export earnings per hectare in the Netherlands $83,300 versus $109 (810 times more than Australia)? How it is that Australia has 185 times more land mass and 249 times more productive agriculture land, and yet the Netherlands exports three times more agricultural produce per year making them second in the world only after the USA?

To find the answers to these questions, one must look at the ways agribusiness in the Netherlands exploits the digital environment, especially the IoF and E-commerce. The Internet of Farms (IoF) is an umbrella term for all the farm devices connected to the Internet. From the simple connected switches to advanced soil sensors, almost all new sensors that hit the market have the Internet accessibility feature. The Netherlands has unlocked on-farm data by deploying a nationwide IoT communication networks that are helping to digitally transform the agricultural sector. The fourth industrial revolution enabled the Netherlands to become a globally recognized leader in the Ag 4.0 sector. Agriculture 4.0 is a term for the next big trends facing the industry, including a greater focus on precision agriculture, the internet of things (IoT) and the use of big data to drive greater business efficiencies in the face of rising populations and climate change.

The IoT enables physical objects to be sensed and remotely monitored to create a direct integration between the physical and digital worlds. It provided the agricultural workers with the information crucial for better decision-making or to change the way of conducting business. This benefits not only the farmer, but also the entire agricultural products supply chain. Using the IoT, the influence of farm connectivity can be extended all the way to the end consumer.

The project Internet of Food & Farm 2020 (IoF2020) examines the potential the IoT technologies hold for the European food and agriculture industries. It has set an ambitious goal: to make precise agriculture a reality and make that vital step in the more sustainable food supply chain. The IoT technologies increase the yields and product quality.

Big data has the potential to benefit the whole supply chain and will play a greater role than ever before in transforming the agriculture industry. The advanced connectivity of a global agriculture network provides a vast number of benefits up and down the supply chain: Farmers can use their data to apply the right products, at the right rates, and at the right time; distributors can use data to source inputs and position themselves for maximum advantage in the market; manufacturers can improve their means of production and better target their customer base (Proagrika, 2019).

The role of big data is one of change, likely the largest change seen in agricultural operations this century. Big data will make the whole chain more competitive and profitable.

For agribusiness firms upstream of the producer, it should be remembered that E-Commerce is not so much a product as it is a method for delivering agricultural inputs.

Conclusions

Agribusiness needs to adapt to the new "digital age" by supporting the development of information and communication technologies.

The attitude toward change of the individuals involved in agriculture management and the lack of skills and initiative to implement IT may frustrate the efforts to implement the concepts of expedited development and new business models focused on IT for agricultural companies. Understanding the way e-Commerce can affect the delivery of agricultural products would greatly benefit both the stakeholders and policy-makers.

Abstract

The issue of quality has always been present in trade, but mostly as a commercial requirement in the establishment and functioning of buying and selling relations. Historically observing, it can be concluded that the quality of the trade in market developed countries has evolved from elementary properties of assortment quality (durability, utility), over the quality of serving, to the eco-quality. Direction of quality evolution was determined by development of ecological awareness about the vulnerability of nature and environment. This is why the economies of certain countries are at different levels of ecological economics and eco- quality. In these circumstances, companies from different business segments, including trade, are identified as one of the key links in the environmental responsibility chain. Therefore, they are increasingly required to meet customer needs for products and services, while also taking into account the environmental impacts they have. Adequate identification of emerging trends that are reflected in, among other things, increasing demands for environmental responsibility, results in the creation of new ways to improve competitiveness. Thus, more and more companies are trying to integrate the concept of environmental responsibility into their business by introducing practices that have the epitome of "green". This paper will discuss the responsibilities of companies, especially trade, in the fight for environmental protection, the way companies incorporate environmental principles into their businesses, as well as the unfair practices that arise in pursuit of greater competitive advantage in a green economy.

Keywords: *Trade, Eco-quality, Eco-standard, Green economy.*

Introduction

The economic crisis of the 1970s and reports of the alarming consequences of uncontrolled economic growth on the environment have led to increasing demands for a change in approach to economic policy. The new economic policy should support the transition to an economy that respects the interests of future generations, as it requires the responsible use of scarce resources. Processes taking place globally make significant contribution to this goal. Initiatives from international environmentalists, the increasing influence of enviromentralist movements, and the media are increasingly influencing people's environmental awareness while creating new trends. In these circumstances, companies are designated as one of the key links in the environmental responsibility chain. Therefore, they are increasingly required to meet customer needs for products and services, while also taking into account the environmental impacts they have. Adequate identification of emerging trends that are reflected in, among other things, increasing demands for environmental responsibility, results in new ways to improve competitiveness. Thus, more and more companies are trying to integrate the concept of environmental responsibility into their operations by introducing "green" or "environmental" practices. This paper will discuss the corporate responsibility for environmental protection, how companies incorporate environmental principles into their operations in pursuit of greater competitive advantage in a green economy.

Green economy for sustainable development in trade

The rapid industrial development, in addition to positive changes such as significant production growth, accelerated economic development, higher employment and the living standard of people, has influenced the emergence of numerous forms of negative environmental consequences. Increased exploitation of resources has been necessary to enable mass production and meet the growing needs of the population. This has brought a number of environmental consequences such as pollution of water, soil, and air, destruction of biodiversity, climate change, and rising ocean levels. These phenomena have long been obscured, inter alia due to the lacking interest to consider the negative impacts of industrialization and high investment to prevent environmental consequences. Human negative environmental impact was only recognized globally in the early 1970s, at the first United Nations International Conference on the Environment in Stockholm. This conference is thought to have had a decisive influence on the growing interest of the international community in the growing environmental problems. The ensuing debates have focused on the role of man in the process, paying considerable attention to finding ways to stop these negative trends. In 1983, the United Nations adopted a Resolution establishing the World Commission on the Environment, and one of the historically significant accomplishments of this commission is the report "Our Common Future" (Brundtland report). Pointing to the dangers current economic development policies pose for future generations, the Commission has proposed adopting a sustainable development concept with responsibility at all levels, from global to local. The Commission's report was adopted at the Second United Nations Conference on Environment and Development in 1992, held in Rio de Janeiro. In addition, Agenda 21 was adopted, which defines the sustainable development goals and highlights the need to work towards sustainable development goals at the international, national, regional, and local levels. At subsequent conferences, countries confirmed their commitment. The first day of the Stockholm Conference in 1972, 5 June, was proclaimed World Environment Day. Agenda 2030 of 2015 extended the principles of sustainable development. Serbia has accepted the new agenda and in 2015 established an Interagency Group for the Implementation of the 2030 Agenda. The first Voluntary National Report on the Implementation of the 2030 Agenda for Sustainable Development was presented in 2019 (Agenda for Sustainable Development).

The concept of sustainable development integrates the economic, environmental, cultural and social component and is based on the principle of responsibility towards future generations when using resources. Consumption of scarce resources and environmental pollution have their limits (Ćuzović and Ivanović, 2017). Current generations must reconcile economic and overall development with these limits so as to ensure at least the same environmental quality for future generations. Sustainable development also means aligning development with the principles of social justice at the local, national, and global levels, as well as the transition from a market economy to an environmental economy. Thus, the concept of sustainable development emphasizes the deep link between economic development, the environment, and social well-being (Milenović, 2000). The issue of the environmental or green component of sustainable development came to the fore in 2012 at the UN Conference on Sustainable Development – Rio+20, dedicated to the green economy.

The Green Economy concept was first used by *Pearce et al.* (1989) in their report Blueprint for a Green Economy. (Merino-Saum *et al*., 2019). UNEP defines a green economy as one that contributes to human well-being and social equality while reducing environmental risks and environmental scarcities (UNEP, 2011). So, the new concept does not replace sustainable development, but further emphasizes that sustainable development goals are almost solely based on "correcting" the economy. This involves international coordination in promoting the economic "greening", the abolition of all policies, regulations, subsidies and benefits at the state level, which encourage environmentally-unfriendly business practices and the private

sector support to adopting green business practices. These efforts, as part of the UN Environment Program, address issues such as climate change, natural disasters, the use of scarce resources, and other phenomena that result from human negative environmental impacts. Governments also receive financial and advisory support to create public policies and adopt laws that preserve ecosystems. In this regard, programs involving international organizations, governments and non-governmental organizations have been launched, such as: Green Economy Initiatives (2008), Green Growth Knowledge Platform (2012), Partnerships for Action for Green Economy (2013) and others. In recent years, the concept of an inclusive green economy has evolved, which further emphasizes the need to strengthen solidarity, equality and promote human well-being and health. This requires that each country, within its capabilities, take some responsibility to meet these global challenges.
Numerous environmental measures are applied at different stages during the product life cycle. The rise of a green economy involves bringing together a large number of businesses involved in creating the final product and marketing it to the consumer. The most polluting economic sector is mostly the exploitation of natural resources that are to be used as raw materials for various products. During the exploitation, as well as extraction of metals and minerals from the ore, numerous processes are applied that greatly pollute the natural environment. In order to obtain 1 kg of pure copper, 50 to 200 kg of waste is produced, and 50 to 100 MJ of energy is spent (Kane, 2009, 9). As the value chain shifts, pollution is most often reduced, since manufacturers often pollute less than exploitation companies, while trade and services sectors are less harmful than manufacturers. Within the supply chain, economic and environmental benefits accrue. However, if consumers require non-polluting products whose production process is environmentally friendly, this is often beyond the direct control of the trader, since most of the pollution arises from exploitation and production of raw materials.
Consumers also play an important role in reducing pollution and preserving the environment. Much of the waste consists of inappropriately dismantled product packaging. Increasing consumer awareness of giving primacy to environment-friendly products will reduce the demand for products whose process of production and obtaining the raw materials significantly pollutes the natural environment. Also, awareness of the proper disposal of waste and recycling will reduce the need to exploit certain raw materials that can be obtained through recycling. The above example shows that all participants in the products value chain, from the exploitation of raw materials to consumers and recycling companies, play an important and indispensable role in reducing pollution.

Eco-labeling of products

Eco-labeling is a voluntary accepted certification by companies regarding the environment protection. In order to get the product an eco-label, the complete life cycle of the product is analyzed, from the raw materials used and how they were obtained, to the production process to the way of use and disposal. Customers appreciate the added value they can get when buying a product, so, in addition to price and convenience, retailers can provide customers with new quality by offering eco-labeled products (Ćuzović and Sokolov-Mladenović, 2015). The criteria for awarding the right to eco-label are defined on the basis of scientific research and knowledge, requiring the monitoring of the product life cycle and the application of complex formulas. Customers cannot carry out such calculations on their own, and are, in most cases, not competent to interpret them. The eco-label simply confirms to customers that the product meets the pre-established criteria, i.e. that it represents an environmentally friendly product. The first eco-label in the world was introduced in Germany in 1977, and then other countries introduced national eco-labels. National symbols are often used in combination with green, which increases their recognition. This also increases environmental awareness of customers, as a distinctive green logo can encourage customers to explore its purpose. According to a 2014 survey by the Hartman Group, 62% of respondents asked for product information that a manufacturer claims to be eco-friendly. In this way, customers simultaneously gain knowledge on the reasons for the eco-label, the criteria that the product must satisfy, and, in general, the importance of environmental protection. Thus, eco-labels educate customers, raise awareness of the importance of environmental protection, and, potentially, contribute to adopting environmental principles in all aspects of life and work. Due to the increasing number of labels suggesting a commitment to environmental responsibility, the International Organization for Standardization is developing standards concerning various aspects of eco-labeling of products and services. Eco-labeling standards belong to ISO 14020 – General principles and guidelines for the development and use of eco-labels and declarations. There are three standards within this group that reflect the ISO label classification (Georgeson *et al*., 2017):

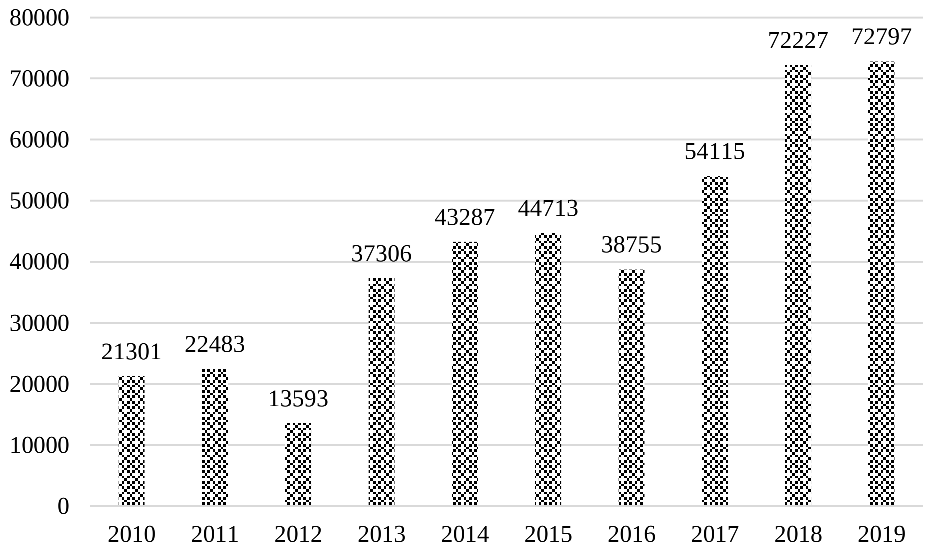
- Type 1 (ISO 14024) - eco-label awarded by a licensed independent organization if the eco-label applicant meets the defined criteria for the entire product life cycle. These may be national or regional eco-labels: "Environmental Choice" in Canada, "Blue Angel" in Germany, "European Flower" for EU members and other labels;
- Type 2 (ISO 14021) – claims that a product meets a certain environmental principle such as "produced from n% renewable material" or "reduced carbon dioxide emission". These are self-initiated claims, which independent organizations do not confirm, so ISO standards can contribute to their credibility;
- Type 3 (ISO 14025) – quantitative monitoring programs for the ecological performance of products throughout the life cycle based on parameters defined by a third, independent party, which verifies the data obtained. It applies to products belonging to a larger industrial group, and, due to the complex verification procedure, there are fewer labels of this type.

Serbia introduced the national eco-quality label in 2011 and is called "Friend of the Environment". This label, according to the ISO classification, belongs to the type I eco-label and is defined by the SRPS ISO: 14024. Accredited organizations verify the fulfillment of the criteria and award the label on the basis of the "Rules on closer conditions, criteria and procedure for obtaining the right to use the eco-label, elements, appearance and method of using the eco-label for products and services". Product groups and criteria for awarding the label by group are aligned with those applicable to the European Flower award.

Companies are increasingly recognizing the effects of eco-labeling, so labels such as "100% biodegradable", "environmental" or "eco friendly" can often be seen. Claiming environmental responsibility can increase sales revenue, business reputation and greater brand value. Among the effects of eco-labels is the advantage over competitors' products, since customers are increasingly comparing products and opt for a product that offers additional, "green" quality. These labels represent a significant marketing tool and have a psychological effect on customers, as they suggest that products and packaging are acceptable from an environmental point of view. Therefore, the increasing number of eco-labels raises concerns about the credibility of these claims. Today, the market has been characterised by the co-existence of a large number of ecolabels, claims and declarations. (Gruère, 2013). The question arises as to whether these labels suggest a genuine concern for the environment or the idea to increase the purchase of products. This is due to the lack of legal basis for regulating this field and the possibility of eco-labels being issued without verification by an independent institution.

Graph 2 shows data on eco-labeled products and services in the EU. In the observed period, the number of eco-labeled products and services has increased from 21,301 in 2010 to 72,797 in 2019. However, in 2012 and 2016, the number of eco-labeled products in the EU decreased. This decline is caused by the expiration of the licenses of a specific product group before the completion of the audit and renewal process. The countries with the highest number of eco-labeled products and services are Spain with 30,877, Italy with 8,630, Germany with 4,390, Belgium with 4,369 and France with 4,192.

Graph 2. EU Ecolabel Products and Services from 2010-2019



Source: European Commission https://ec.europa.eu/environment/ecolabel 20.09.2019.

Companies are increasingly recognizing the effects of eco-labeling, so labels such as "100% biodegradable", "environmental" or "eco friendly" can often be seen. Claiming environmental responsibility can increase sales revenue, business reputation and greater brand value. Among the effects of eco-labels is the advantage over competitors' products, since customers are increasingly comparing products and opt for a product that offers additional, "green" quality. These labels represent a significant marketing tool and have a psychological effect on customers, as they suggest that products and packaging are acceptable from an environmental point of view. Therefore, the increasing number of eco-labels raises concerns about the credibility of these claims. The question arises as to whether these labels suggest a genuine concern for the environment or the idea to increase the purchase of products. This is due to the lack of legal basis for regulating this field and the possibility of eco-labels being issued without verification by an independent institution. Eco-labeling can be misused by companies in order to attract customers. It is important to lay down rules to sanction such behavior, which could be a topic of further research.

Conclusions

Global efforts to reduce the impact of economic growth on the environment and secure the future of new generations have reflected, among other things, on corporate operations. Similar to macro-level activities, companies are required to design processes, operations, products and services as environmentally friendly. This means that, in a green economy, respect for environmental standards is a prerequisite for successful market positioning, especially for companies seeking to internationalize their businesses. This is why environmental thinking is increasingly becoming an integral part of the business decision-making process and the creation of product bundles. At the same time, growing customer interest in eco-labeled products has encouraged individual companies to use these labels as part of their offer, without a real commitment to environmental principles. Thus, false claims of compliance with environmental standards mislead customers and jeopardize the position of companies that make significant efforts to meet environmental requirements. International organizations have recognized this problem, and pay considerable attention to analyzing and making recommendations to avoid this unfair practice. However, states will play a key role in this process, enacting laws that protect customers' interests from unscrupulous retailers. Considering the growing interest of stakeholders in "greening" all business aspects, it is concluded that companies that are essentially committed to environmentally responsible business will have a great advantage in the future.

Abstract

Both theoretical and practical importance have recently been attached to an analysis of the operating profit margin or earnings before interest, taxes, depreciation and amortization (EBITDA margin) as a measure of the long-term performance of companies. In the integrated financial reporting it is presented through various indicators based on it. In view of this, we have made a comparative analysis of the operating profit margin and its impact on the performance of food trade companies in Serbia and comparable countries. Under the influence of different factors, the dynamics of the size of the operating profit margin of food trading companies in Serbia varies from comparable global food retailers in various countries. The EBITDA margin of the leading food trading companies in Serbia is lower than the in analyzed comparable food retail trade companies. It points to the conclusion that it is necessary to efficiently manage revenues, costs, profit, assets, and financial structure in order to improve the performance of food trading companies in Serbia in the future**.** The general conclusion is that it shows a growth tendency and is, nevertheless, lower in comparison to food trading companies from countries of a developed market economy. In order to increase the operating profit margin, as a measure of long-term performance, it is necessary to manage the financial structure of the food trading companies in Serbia as effectively as possible. (JEL codes: L81, M31, M41, O32)

Keywords: net profit, interest, tax, depreciation, amortization.

Introduction

Considerable theoretical and practical attention has been paid in recent years to analyzing the operating profit margin or earnings before interest, taxes, depreciation and amortization (EBITDA margin) as a measure of the long-term performance of companies. On the basis of it, special indicators of long-term performance of companies have been developed. They are comparatively analyzed by individual companies (from the same and different sectors) and based on this –their long-term business success is recognized. Bearing this in mind, the subject of research in this paper is a comparative analysis of the operational profit margin of food retail enterprises in Serbia and comparable foreign retailers. The aim of this research is to thoroughly investigate the problems of the operating profit margin as one of the determinants of the long-term performance of food trading companies in Serbia and, on that basis, to propose the measures for its improvement in the future. This gap is to a certain extent filled with this paper, in what we find its scientific and professional contribution. The basic hypothesis of research in this paper is that the operating profit margin is a significant measure and determinant of the long-term performance of food trading companies. For these reasons it is necessary to investigate it more extensively on the example of food trade companies in Serbia, particularly the dynamics and factors of its size. In this paper, we will explore the dynamics of the size of EBITDA margin of well-known global food retailers, such as Wal-Mart, Tesco and Ahold Delhaize, in order to make comparisons of the EBITDA margin with Serbian trading companies. This provides the basis for proposing adequate measures to increase the size of the EBITDA margin, as a measure of long-term performance of food trading companies in Serbia. The EBITDA margin of the analyzed leading food trading companies in Serbia (Ahold Delhaize Serbia, Mercator-S and IDEA) is lower than that of analyzed comparable food retail (primarily food) trade companies from the developed market economies. Overall, more efficient management of the financial structure of capital, sales revenues, costs of goods sold (including operating costs, interest) and profit can significantly influence the increase in the EBITDA margin as a measure of the long-term performance of food trading companies in Serbia. This will definitely have a positive impact on the dynamics of the size and efficiency of investments, as a key factor in the performance of food trade companies in Serbia.

Material and methods

For the needs of the research of the treated problems in this paper, empirical data from the Agency for Business Registers of the Republic of Serbia were used. They are completely comparable to the same type of other global food retailers 'data and, in this sense, there are almost no restrictions on the obtained research results in this paper due to the fact that we used empirical data from their publicly disclosed financial statements in this study. With the defined aim and research hypothesis, the basic methodology in this paper is the comparative analysis and application of the relevant statistical analysis. Also, to a certain extent, the historical and normative methodology was applied in researching the treated problem in this paper. The operating profit margin or earnings before interest, taxes, depreciation and amortization (EBITDA margin) as a measure of performance has been used since the mid-1980s, especially since the 1990s in all companies, including wholesale and retail (Levy, 2014). There is extensive literature written on the subject of general problem of measuring the significance of gross operating margin in financial reporting for the needs of more efficient company management (Sui, 2017). However, a number of published papers dedicated to the specificities of gross operating margin analysis in commercial enterprises (food retailers) is significantly lower (Berman, 2013; Corona, 2014; Špička, 2016; Tan, 2016; Calva, 2017; Carstea et al, 2017; Ko et al., 2017; Hoe, 2017; Manini, 2017). This particularly applies to literature in Serbia (Lukic, 2017a, b; Lukic, 2018) – as far as we know, there is no complete work that has been published so far on the issue of the importance of measuring and analyzing gross operational margin in Serbia's trade companies (food retailers). As a measure of long-term performance of (food) retailers, the operating profit margin has its advantages and disadvantages. It is considered that during the usage of this criterion retailers are focused on the performance of fundamental business rather than on financial decision-making related to depreciation of fixed assets, interest and financial structure (lending instead of increasing equity by selling shares) (Levy, 2014). In view of this, it provides bankers, investors, creditors, fiscal authorities and others an insight into the long-term potential options for collecting their retailers' claims. More and more financial analysts are aware of certain problems of interpreting the EBITDA margin, and in order to overcome them, the model of economic additional value (the so-called EVA model) is recommended. Nevertheless, it should also be noted that the very model of economic value addition has its own weaknesses, which primarily relate to subjective assumptions regarding the calculation of capital costs. In conclusion, it is necessary to use both models (EBITDA margin, EVA model) concurrently when assessing the long-term performance of retailers. We are well aware of the fact that in recent years many global retailers, and what we consider quite right, also regularly report on the economic value added (for example, METRO group and others) in the context of integrated financial reporting. In this way, the problem of interpreting the EBITDA margin is partially mitigated. Due to the specifics of the nature itself, way of doing business and the applied financial management strategy, the dynamics of the size of the operating profit margin varies by individual types of trade (wholesale and retail), retail companies and countries in which they operate, retail chains (types of shops) and product categories. This is scientifically proven by the empirical analysis of EBITDA-size dynamics of retailers 'margin which has been carried out from different perspectives. Model of calculating the EBITDA margin, it is determined in the following way: EBITDA = Revenue - Expenses (excluding interest, taxes, depreciation and amortization), i.e. EBITDA = Net profit + Interest + Tax + Depreciation + Amortization. From this last formula it follows that: Net profit = EBITDA - (Interest + Tax + Depreciation + Amortization). For illustration purposes Table 1 shows the model for calculating the EBITDA margin in the global retailer Wal-Mart. Therefore, it is consistent with the model shown above.

Table 1. Model of calculating the EBITDA margin at Wal-Mart (USD $ million)

	January 31, 2018	January 31, 2017
Net income	9,862	13,643
Add: Net income attributable to non-controlling interest Less: Income from discontinued operations, net of income tax Add: Income tax expense	661 - 4,600	650 - 6,204
Earnings before tax (EBT)	15,123	20,497
Add: Interest expense, debt, capital lease and financing obligations	2,330	2,367
Earnings before interest and tax (EBIT)	17,453	22,864
Add: Depreciation and amortization	10,529	10,080
Earnings before interest, tax, depreciation and amortization(EBITDA)	27,982	32,944

Results and discussion

The value multiplier is determined as follows:
Enterprise Value / EBITDA = (Market Value of Equity + Value of Debt-Cash) / EBITDA.
It shows how the market values the (retail) firm in accordance with the ability to generate operational profits (Enterprise value/EBITDA (EV/EBITDA). As an illustration, Table 2 shows a value multiplier on the example of a food value chain in the US.

Table 2. Food value chain value multiplier in US, January 5, 2018

	EV/EBITDA
Farm/Agriculture	13.07
Food processing	13.01
Food wholesale	10.43
Retail (grocery and food)	8.40
Restaurant/Dining	12.69

Note: Enterprise Value / EBITDA = (Market Value of Equity + Value of Debt-Cash) / EBITDA.

Source: Enterprise Value Multiples by Sector (US), January 5, 2018, http://pages.stern.nyu.edu/~adamodar/New_Home_Page/datafile/vebitda.html, (May 10, 2018)

The data in a given table show that the value multiplier is different for some members of the food value chain in the US. Thus, for example, it is significantly higher for farming/agriculture (13.07) than for retail (8.40). This is partly due to differences in the very nature of their business. In order to make in-depth analysis of the EBITDA margins in the food retail sector, Table 3 shows a value multiplier of the Wal-Mart retailer and its competitors for 2017 and 2018.

Table 3. Value multiplier,Wal-Mart (January 31, 2017 and 2018)

Wal-Mart Inc., EV / EBITDA calculation	January 31, 2018	January 31, 2017	January 31, 2016	January 31, 2015	January 31, 2014	January 31, 2013
Enterprise value (EV), (USD $ million)	305,207	260,427	260,724	306,165	300,184	297,926
Earnings before interest, tax, depreciation and amortization (EBITDA), (USD $ million)	27,982	32,944	33,640	36,433	35,861	36,489
Ratio EV / EBITDA	10.91	7.91	7.75	8.40	8.37	8.16
Benchmarking EV / EBITDA competition						
Amazon.com Inc.	-	43.74	31.40	33.08	33.45	41.58
Costco Wholesale Corp.	-	12.63	13.27	13.49	12.08	12.30

EV / EBITDA, Industry						
Customer service	-	12.26	11.49	10.91	10.77	10.30

Source: https: // www.stock-analysis-on.net, (May 28, 2018)

The data in the given table show that the value multiplier differs between some food retailers. Thus, for example, on January 31, 2018, in Target Corp. it was 6.96 and in Wal-Mart 10.91, respectively. The Wal-Mart value multiplier is lower than the average of the sector and industry. These differences are certainly the result of the implementation of different financial management strategies (lending versus the increase in equity by selling shares). Earnings before interest, taxes, depreciation and amortization differ among individual food retail companies. Table 4 illustrates the dynamics of the EBITDA margin of the global retailer Wal-Mart for the period 2008 - 2017.

Table 4. Dynamics of EBITDA margin of Wal-Mart, 2008 – 2017

End of period	WMT
January 2008	NA
January 2009	7.3%
January 2010	7.6%
January 2011	7.9%
January 2012	7.7%
January 2013	7.7%
January 2014	7.5%
January 2015	7.5%
January 2016	7.0%
October 2016	6.8%
January 2017	6.8%
October 2017	6.6%

Source: https://finbox.io/WMT/explorer/ebitda_margin, (May 10, 2018)

Recently, the EBITDA margin has decreased in Wal-Mart compared to the previous period. Compared to some competitors it is larger and compared to others – smaller (for example, Target Corporation 9.9%) (Table 5). This is, partly, the result of the very nature of the industry operations of its own, sector, company size and business operations model (i.e. the applied financial strategy of the business).

Table 5. EBITDA margin of Wal-Mart and its competitors, 2017

Company	EBITDA margin
Spartan Nash Company (SPTN)	-0.3%
Smart & Final Stores, Inc. (SFS)	3.1%
Kroger Company (The) (KR)	4.5%
CompanhiaBrasileira de Distribuicao (CBD)	6.1%
Casey's General Stores, Inc. (CASY)	6.2%
Best Buy Co., Inc. (BBY)	6.2%
CVS Health Corporation (CVS)	6.6%
Wal-Mart Stores, Inc. (WMT)	6.6%
Target Corporation (TGT)	9.9%
Consumer Staples (SECTOR:STPL)	12.5%
Procter & Gamble Company (The) (PG)	25.6%
#ERROR! (CNCO)	N

Table 6 shows the dynamics of EBITDA margin of Tesco for the period 2014 - 2018.

Table 6. EBITDA margin of Tesco, 2014 – 2018

Fiscal year March-February. All values are expressed in millions of pounds (GBP)	2018	2017	2016	2015	2014
Sales/Revenue	57,491	55,917	53,933	56,925	63,557
EBITDA	2,957	2,581	2,202	(1,733)	4,757
EBITDA growth	14.57%	17.21%	227.06%	-136.43%	-
EBITDA margin	5.14%	-	-	-	-
EBIT	1,663	1,284	-	-	3,225

Source: https://quotes.wsj.com/UK/XLON/TSCO/financials/annual/income-statement, (May 11, 2018)

The data in the given table show that the share of EBITDA margin in revenues is lower in Tesco (5.14%) than in Wal-Mart (6.6%). This is partly a consequence of a different model of doing financial operations. Table 7 shows the EBITDA margin of Ahold Delhaize, which operates in Serbia as Delhaize Serbia.

Table 7. EBITDA margin of Ahold Delhaize

	12/16A	12/17E	12/18E	12/19E
Revenue (€ million)	63,093	63,943	65,348	66,920
EBITDA (€ million)	4,142	4,267	4,507	4,836
EBIT (€ million)	2,420	2,386	2,638	2,923

EBITDA margin (%)	6.6	6.7	6.9	7.2
EBIT margin (%)	3.8	3.7	4.0	4.4
EV/EBITDA (x)	6.7	6.4	6.0	5.5
EV/EBIT (x)	11.4	11.4	10.3	9.2

Source:https://research-doc.credit-suisse.com/docView?language=ENG&format=PDF&sourceid=emgpm&document_id=1077229781&serialid=7%2F%2FS9ldDW4ewIdMX6A26zlMtYs6VxLxiTmpgD2zQdGM%3D, (May 22, 2018)

In Ahold Delhaize, the EBITDA margin is higher than at Tesco (5.14%) and is approximately the same as with Wal-Mart (6.6%). In the future, there is an estimated growing trend. The EBITDA margin is certainly different among observed countries in which Ahold Delhaize operates. Ahold Delhaize's operating profit margin, observed by individual countries in which it operates, is significantly higher in the US and the Netherlands than in Belgium and Central and Southeastern Europe (to which the Delhaize Serbia belongs). These differences are the result of different general business conditions and applied (financial) business strategies.Table 8 shows the EBITDA margin of the Russian company X5 Retail Group for the period 2012-2016.

Table 8. Dynamics of EBITDA margin of the company X5 Retail Group, 2012-2016

	EBITDA Margin (Rub bn)	EBITDA margin, %
2012	35,1	7.1%
2013	38,4	7.2%
2014	46,4	7.3%
2015	59,4	7.3%
2016	79,5	7.7%
2016/2015	33.8%	

Source: Q1 2017 Financial Results, X5 Retail Group, Moscow, Russian Federation 27 March 2017, https://www.x5.ru/en/Documents/X5-Q1-2017-Financial-results.pdf, (May 12, 2018

The data in the given table clearly show that the EBITDA margin of the company X5 Retail Group is higher than in Wal-Mart, Tesco and Ahold Delhaize. In other words, its profitability measured by cash flows from operations (using EBITDA margin) is slightly better than the observed retail companies.

In the analyzed period, the costs of goods sold by trade companies in Serbia have slightly increased dynamically until 2015 and from that year up to 2017 much faster, as can be seen from Figure 1. The annual growth rate of the costs of goods sold (3.3%) is thus lower than the annual growth rate of the EBITDA margin (4.99%).To sum up, the return on investments in Serbia's trade companies increased to some extent. In order to make anin-depth analysis of long-term trade performance in Serbia measured by the EBITDA margin, we will show the respective margin for three significant trade companies in Serbia for 2016 (Table 9). Based on the data presented in the given table, we can also conclude that the EBITDA margin of the leading (food) trading companies in Serbia is lower than the analyzed comparable food retail trade companies from the developed market economies.

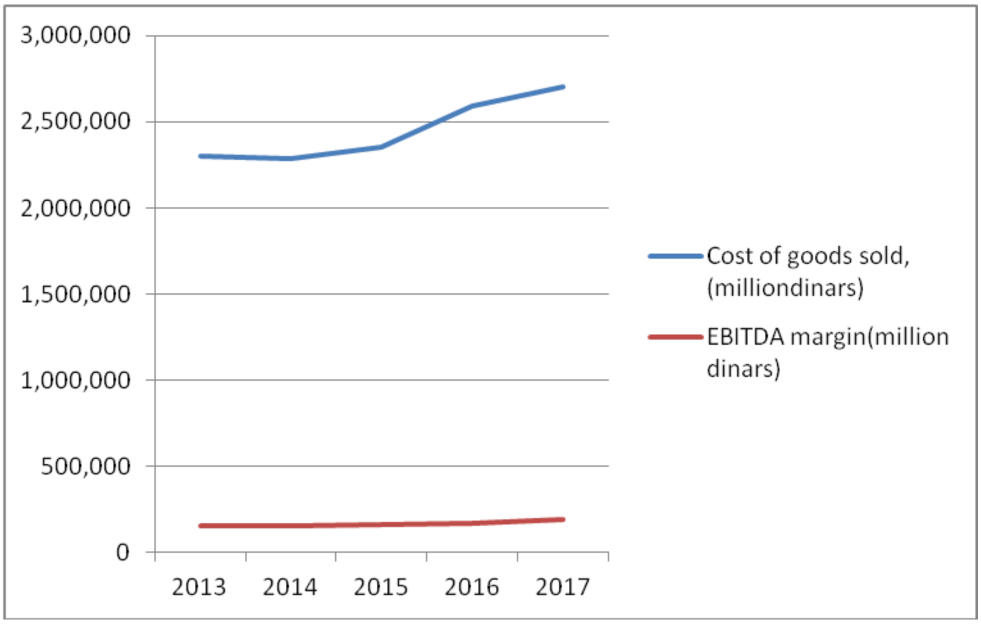

Figure 1. Cost dynamics of goods sold and EBITDA margin of trade companies in Serbia
Note: Figure illustrated by the author.
Source: Business Registers Agency.

The regression analysis show that the costs of goods sold, as a specific expression of investment, significantly affect the EBITDA margin (Pearson Correlation, 927, Sig. (1-tailed), 012 p <0.05). (The regression equation is: Y = -46285.142 + 0.087 X, where: Y = EBITDA margin, and X = costs of goods sold.) The method of financing working capital (especially inventories) is a significant determinant of the EBITDA margin of trading companies. In this context, we will examine the impact of interest costs on the costs of goods sold of the commercial enterprises in Serbia. The results of the correlation analysis show that there is a negative (statistically significant) strong correlation between the costs of sold goods and interest as a component of the EBITDA margin of trading enterprises in Serbia – this is quite logical – given their character.

Table 9. EBITDA margin of significant trade companies in Serbia, 2016

	EBITDA margin, (million dinars)	EBITDA margin, (% from sales)
Ahold Delhaize Serbia	3,719	4.3%
Mercator-S	3,081	2.9%
IDEA	117	3.99%

Note: Author's calculation.
Source: Business Registers Agency, Belgrade.

Conclusion

Due to the growing EBITDA margin trend and based on the analysis conducted in this paper, we can conclude that the long-term performance of trade companies in Serbia has recently improved. The average operating profit margin (EBITDA) of trading companies in Serbia expressed as percentage of revenue is slightly higher than 5% (Mean 5.1840). However, it is lower compared to the US, Canada, Europe, the Netherlands, Belgium, Central and Southeast Europe, Germany and Russia. More efficient management of the financial structure of capital (financial leverage = assets / capital) can influence the improvement of the return on sales measured by the relationship between the EBITDA margin and total revenues. Costs of goods sold, as a specific expression of the size of investments, significantly affect the EBITDA margin (Pearson Correlation, 927, Sig. (1-tailed), 012 $p < 0.05$). There is negative (but statistically significant) strong correlation between the costs of goods sold and interest as a component of the EBITDA margin, which is quite logical given their character. The EBITDA margin of the analyzed leading trading companies in Serbia (Ahold Delhaize Serbia, Mercator-S and IDEA) is lower than that of analyzed comparable retail (primarily food) trade companies from the developed market economies. Overall, more efficient management of the financial structure of capital, sales revenues, costs of goods sold (including operating costs, interest) and profit can significantly influence the increase in the EBITDA margin as a measure of the long-term performance of trading companies in Serbia. This will definitely have a positive impact on the dynamics of the size and efficiency of investments, as a key factor in the performance of trade companies in Serbia.

Abstract

In several countries there are initiatives to develop agricultural insurance schemes operated either directly by governments or by promoting this market with participation of private companies. Interest in the study of agricultural insurance arise from its impact on the sustainability of agricultural holdings by allowing farmers to conserve their means of production and maintain the capacity to reinvest in the next agricultural cycle in case of losses. In this paper an analysis of the National Rural Insurance System (SNARM), in Mexico is made. The participation of the government is provided by AGROASEMEX, a national insurance institution that functions as an agency for the development and research of the sector. Its functions include promoting the agricultural insurance market, providing reinsurance services to other stakeholders and granting subsidies to support cost of the insured's premium. It also provides support to the operation of the Insurance Funds. Also, the Ministry of Agriculture and Rural Development (SADER) has developed insurance schemes against natural disasters in recent years and provide additional support to producers with access to commercial insurance. There are six companies organized as corporations that have authorization to operate in agricultural and animal insurance. Finally, there is the participation of the producers who have set up 529 Insurance Funds. These are regional associations and they operate with non-profit and mutual principles. As a result, in Mexico there is a developed private-public partnership for risk management, adding to the government and private companies the participation of farmers providing self-insurance.

Keywords: *Risk management, agricultural insurance, insurance funds, catastrophic insurance.*

Introduction

Economic agents are subject to risks and uncertainty to at different degrees, according to the industry in which they operate. Agriculture production is characterized by highly volatile and unpredictable production results. Unlike most other entrepreneurs, agricultural producers cannot predict with certainty and reliability the amount of production they will obtain, due to the occurrence of risks such as weather, pests and diseases. The adverse events that occur during the establishment, development and harvesting of the crop can even cause the loss of the total production (Iturrioz, 2010).

The management of agricultural production risks is based on the optimal combination of technical and financial tools. Farmers and ranchers can absorb small but frequent losses through appropriate risk mitigation techniques in the production unit and with self-insurance tools. More severe but less frequent losses can be gradually transferred to cooperative / mutual insurance schemes, commercial insurers and reinsurers (Mahul & Stutley, 2010).

Agricultural insurance, among other risk management tools, can help improve agricultural productivity by helping farmers invest in more productive but potentially more risky agricultural practices. In a context, which is changing rapidly due to a more complex agri-food chain and climate change that may be increasing the frequency and severity of natural disasters and causing greater price volatility due to changes in the market structure, agricultural insurance is an important instrument to maintain long-term stability and growth of the agricultural sector, and facilitate access to credit, help reduce the negative impacts of natural disasters and encourage investment in improved production technologies (Porth & Seng Tan, 2015).

In the world, three agricultural insurance systems have been identified; the system controlled by the government, in which the supply of insurance predominates through a state entity; pure market systems, in which different insurance products are offered by insurance companies and public-private partnership systems with the participation of both the state and insurance companies (Iturroiz, 2010)

Mexico is a country that is highly exposed to a great variety of natural hazards. The southern Pacific coast of the country is located in the so-called Ring of Fire of tectonic activity. Tropical storms and hurricanes are a constant peril both the Pacific and the Atlantic coast. Droughts are increasingly affecting the entire country and even in typically humid regions, at the same time, a process of desertification is affecting vast northern regions. Under these conditions, natural hazards in Mexico have increased their economic impact in the last four decades (Saldana-Zorrilla, 2015).

The interest in agricultural insurance lies in its potential impact on the sustainability of agricultural holdings, because, in the case of a bad harvest, it allows farmers to keep their production tools and their ability to reinvest in the preparation of the next agricultural cycle (Sandmark , Debar, & Jaleran, 2014). This risk management instrument has been part of the public policies in Mexico since the 1940's. This paper identifies the current structure of the risk management system in Mexico from the perspective of the supply of agricultural insurance and the agents that comprise it.

Materials and Methods

Documentary review work was undertaken and databases of the main institutions involved in the National Rural Insurance System were compiled, such as AGROASEMEX, SA, the National Integrator of Insurance Funds (OINFA), as well as the regulatory entities of the system: the National Insurance and Bonding Commission (CNSF) and the Ministry of Finance and Public Credit (SHCP).

The information allowed identifying the agents that offered agricultural insurance directly to the producers as well as to those offering reinsurance, the area that has insurance coverage as well as the indicators related to the insurance of premiums and the payment of claims.

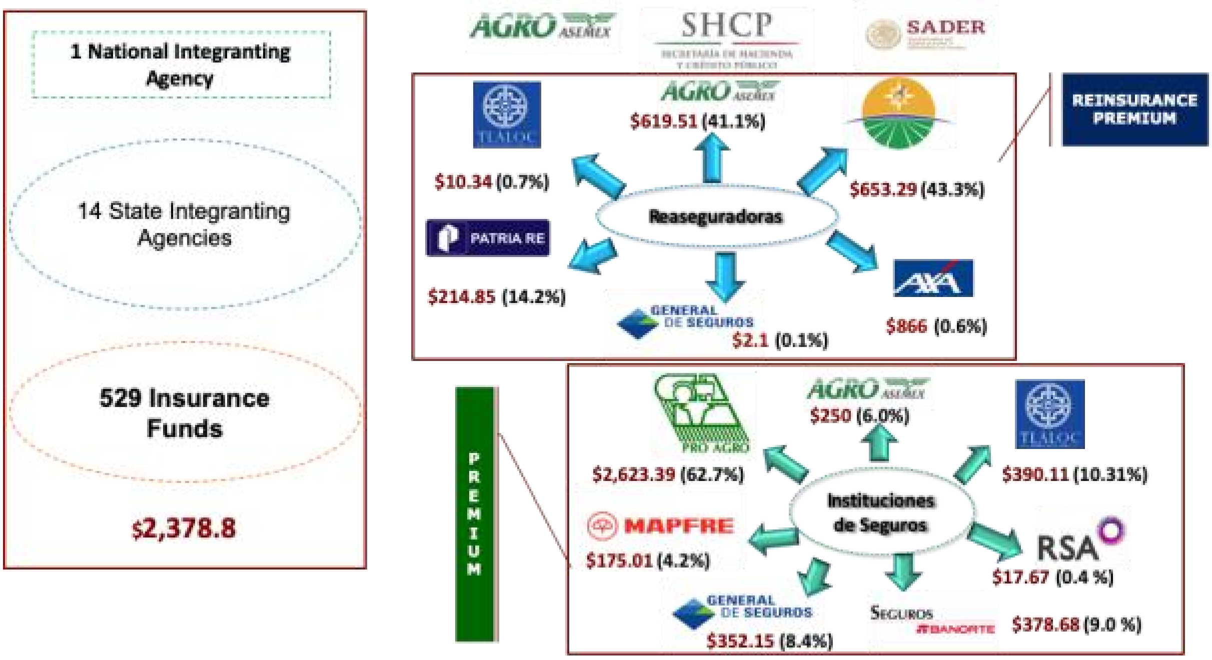
Results and Discussion

Structure of the National Insurance System for the Rural Environment

The transfer of the risk of loss, due to climatic or biological factors can be performed under three different modalities: (i) contract insurance with a private company, (ii) the organization of an insurance fund involving farmers directly each of whom pays the respective premium to a common fund, with the function of, compensating precisely those farmers who register claims, and (iii) limited coverage that can be accessed through the Agricultural, Livestock, Aquaculture and Fishing Catastrophic Insurance (SAC) component operated by SAGARPA and the governments of the states, which aims to be the address of the damages caused by natural disasters characterized for being atypical and unpredictable.

Thus, in the National System of Rural Insurance (SNAMR), the public, private and social sectors come together, giving rise to a public-private partnership. AGROASEMEX -is a national insurance institution-; is the part of the public sector that functions as an agency for development and research in the subject. Its functions include the promotion of the agricultural insurance market, the provision of reinsurance service to other actors and the payment of support as a subsidy to cover partially the cost of the premium of the insured as well as support for the operation of the Funds and the integrating organization. In the same public sector, in recent years the Ministry of Agriculture, Livestock, Rural Development, Fisheries and Food has developed insurance schemes against natural disasters and complementary support for producers with access to commercial insurance.

Figure 1. Structure of the provision of agricultural insurance in Mexico, (figures in millions of pesos)



Source. Author´s elaboration based on data from AGROAESEMEX and the National Insurance and Bonding Commission (2019)

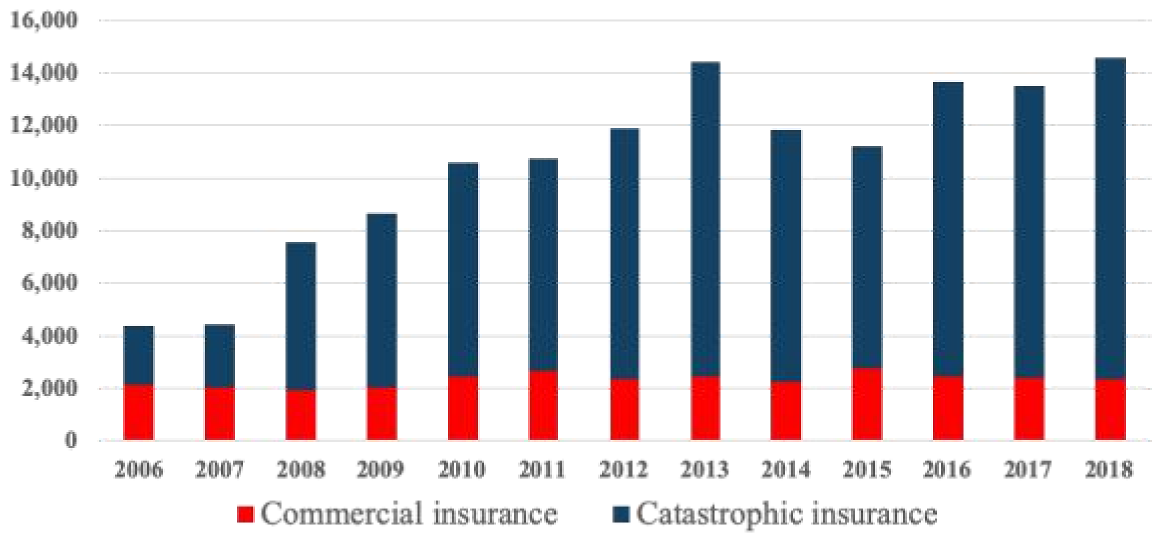
The private sector participates with 96 insurance institutions, constituted as corporations, of which 16 have authorization to operate the agricultural and livestock insurance. In the last 15 years, the maximum number of companies that made agricultural insurance was twelve, and at present only six companies operate agricultural insurance and five carried out reinsurance operations.

The organized producers constitute Insurance Funds, they are associations operating at the regional basis, working with non-profit and mutual principles. 529 funds have been set up (AGROASEMEX, 2018), and they are integrated at a higher level in 16 State Integrating Agencies and 1 National Integrating Agency supported by a specific legislation, the Law on Agricultural and Rural Insurance Funds.

Coverage of the insurance system

In Mexico, 21.9 million hectares of annual crops are sown, this is the first goal of where to provide protection by the agricultural insurance. There are two segments of the insurance market, commercial insurance mainly through which, a level of yield is protected allowing the recovery of the investment made in the crops until the time of occurrence of a loss through insurance policies or certificates. It is directly contracted by farmers.

Figure 2. Insured area by the National Insurance System for the Rural Sector (thousands of hectares)



Source: Author´s elaboration based on data from AGROASEMEX and SAGARPA

For historical reasons and due to the culture of risk management that is prevalent among farmers, the commercial insurance market has been closely related to the credit market. The natural insurance market is made up of those producers who plant relatively large areas, with irrigation, and who, by financing their investments with credit, have a greater propensity to protect them against the occurrence of adverse climatic and biological phenomena, thereby reducing the possibility of falling into insolvency and therefore being left out of the credit (Muñoz-Rodríguez, Santoyo-Cortés, Gómez-Pérez, & Altamirano-Cárdenas, 2018).

Until the year 2002, face the occurrence of a catastrophic year for agricultural activities in one or more states of the Republic, claims made to local government rose to such a degree that they compromised the state public finances, which invariably forced its leaders to request budget increases from the federation to attend the emergencies. Therefore, to avoid permanent pressure on public finances and have a foreseeable budgetary ceiling to address these contingencies, it was decided to create the second modality of access to insurance, catastrophic insurance in which relatively low sums are protected against risks of low occurrence but high impact. It is contracted by state governments with a federal and state subsidy.

Unlike commercial insurance, which has not grown in the last ten years, catastrophic insurance has recorded significant growth to represent an insured area that is four time larger than the covered by commercial insurance.

Catastrophic insurance is a massive type of insurance, acquired and paid for directly by state governments and the federal government to protect low-income producers when a natural disaster occurs that affects agricultural, livestock, fishing or aquaculture and it has limited coverage. The insured producers are not identified at the time of contracting, and it is the states that receives compensation in the case of catastrophic losses, then compensates the producers in the disaster areas. 11.5 million hectares are protected with catastrophic insurance schemes.

Result of the agricultural and livestock insurance

The indicator of technical and economic results for private equity companies and the state company show good performance in its operation. In the 25 years between 1991 and 2018, only in 3 years, was the amount paid for compensation higher than the amount of premiums collected. Especially in recent years, with the operation of catastrophic insurance this indicator has improved compared to the model focused on the commercial insurance offer.

Table 1. Amount of direct premiums, claims paid and branch loss index (data in thousands of pesos) *

Year	Premium (A)	Indemnity (B)	Loss Ratio (B/A)	Year	Premium (A)	Indemnity (B)	Loss Ratio (B/A)

* Does not include the information of Insurance Funds

Source: Prepared by the author with data from the National Insurance and Bonding Commission (CNSF).

At current values, premiums amounting to 46,325 million pesos have been issued, paying claims for 27,790 million, giving a loss ratio of 0.6. Despite these acceptable levels of loss rate, the fact is that almost 80% of the area insured at national level is under the catastrophic insurance modality and that really it is an insurance so that governments do not suffer an embezzlement in their budgets, more than insurance for producers, the coverage achieved by the system, especially in commercial insurance contracted directly by producers, is still low despite the high presence of risks that may be subject to protection and the relatively acceptable results of operation.

Conclusions

Mexico has a reliable system to provide of agricultural insurance; however, the coverage of this service is still low. From the perspective of the structure of the offer side, the participation of producers organized in Agricultural Insurance Funds with a wide coverage in the states of the country stands out, while by the private sector there are only six insurers out of 99 participate, which are registered in the country and only one of them concentrates more than 56% of the premiums in the market. The offer of reinsurance is even more limited, since only five companies provide the service and approximately 90% of the premiums from direct insurers are concentrated in them.

Abstract

Fuel samples (*Quercus suber, Quercus ilex, Quercus, Pinus halepensis, faginea, Juniperus oxycedrus and Tetraclinis articulata*) were collected in a cork oak (*Quercus suber L)* forest in the southern part of the mountains of Tlemcen (Western Algeria). A series of flammability tests were carried out using a Mass Loss Calorimeter device (FTT ®). The results showed that the conifers species (*T. articulata, J. oxycedrus and P. halepensis*) were highly flammable because of their high combustibility and sustainability. A significant correlation was located between FMC and PHRR (combustibility, $r = -0.52$, $p < 0.05$) and between FMC and AEHC (sustainability, $r = -0.31$, $p < 0.05$).Analysis offreshfuels revealed *Juniperus oxycedrus*to be the most flammable species (FMC = 60,71 %, TTI = 46,85 s, PHRR = 190,72kW/m2, AEHC = 10,2 MJ/kg and RMF= 2,52). By contrast, Oak species presented low values of the four flammability parameters (high ignitability but low combustibility, sustainability and consumability). The fuel moisture content of Quercus spp. was significantly lower than that of other more flammable species. The findings suggest that the *P.halepensis* presents a very significant risk to the cork oak forests in Algeria.

Key words: *Cork oak forests, conifers, oak species, mass loss calorimeter, flammability, Tlemcen.*

Introduction

The Mediterranean basin is currently under severe water stress due to limited water resources and high demand (Milano et al., 2012). Unfortunately, this region of the world is not immune to the logic of fire, since more than 55 000 fires cover an average of 500 000 to 700 000 ha of Mediterranean forest each year, causing enormous ecological and economic damage, as well as loss of life. (Velez, 2000).The fire, especially at the peak of the summer period, poses a permanent threat to the forests of the Mediterranean region - especially in its western part - and is the main cause of destruction of forests and shrubby sub-forest stands (maquis, scrubland, scrub) (Ramade 1997).

According to M'hirit (1999), Mediterranean forests are mainly composed of areas of open forest or shrubs, maquis and grassy pastures dotted with woody vegetation such as the Oleaster thermophilic scrub (*Olea europaea* var oleaster) and lentiscus (*Pistacia lentiscus*); thermophilous coniferous forests of Aleppo Pine (*Pinus halepensis*), Maritime Pine (Pinus pinaster), Berber's Thuya(*Tetraclinis articulata*) and Juniper and Phoenician Juniper (*Juniperus phoenicea*); evergreen oak sclerophyllous forests: Holm oak (*Quercus ilex, Quercus rotundifolia*), Cork oak (*Quercus suber*), Kermes oak (*Quercus coccifera*); the deciduous forests of Zeen Oak (*Quercus faginea, Quercus canariensis*), Afares Oak (*Quercus afares*).

In Tlemcen mounts, conifers (*Pinus halepensis, Tetraclinis articulata* and *Juniperus oxycedrus*) occupy about 115 700 ha, or 56% of the forest area of the department. Oak species (*Quercus ilex, Quecus suber, Quercus faginea*) extends over 92 000 ha. It is the cork oak ecosystem that dominates in this region. Cork is the only product harvested from these stands. The major problem of these forests is the invasion of conifers with high flammability potential.

This mechanism causes an accumulation of an amalgam of dry and flammable forest fuel because of a strong presence of a sub-wood rich in essential oils and resins. In such climatic conditions and considering the properties of forest fuels, a mere even a small, increased heat can easily be at the origin of a fire and its spread (Kazakis and Ghosn, 2008). Between 1979 and 2009, the Algerian forest lost 1 162484 ha with a total number of reported fires of 41 644 (Bekdouche, 2010). During the year 2012, no less than 17 512 ha of cork oak forests disappeared (Abbas, 2013). In the western region of Algeria and specifically in the Tlemcen region and from 1970 to 2012, the average is 21 households /year. The area moderately burned between 1990 and 2015 exceeds 55 ha/year (DGF,2014). The concept of flammability still generates controversy (Schwilk 2015). Accordingly, flammability can be defined as the capacity of plant biomass to burn, i.e. to ignite and sustain a flame (Pausas et al. 2017). In the same vein, Anderson (1970) and Martin et al. (1994) approach it as a complex process with four compartments namely: ignitability or ease of ignition; the durability or ability of a material to maintain combustion and produce energy; combustibility or the speed with which combustion occurs; and the consumability or proportion of biomass consumed during combustion. Actually, several studies have been devoted to this parameter (Vallette, 1990; Hachmi et al.2011; Madrigal et al.2011). Analysis of the variations of the flammability of the fuel forest has a great importance in the hierarchy of forest between species and therefore in the improvement of the accuracy of the forest fires risk indices. Besides, they allow forest managers to better clarify forest formation and structures to guide forestry (Vallette, 1990; Marino et al.2011). As far as flammability assessment in the laboratory is concerned, a limited scale of experiment has been noticed (particle level or parts of plants, whole plants and stand scale, sensu White and Zipperer 2010) because the way in which plants are exposed to heat may not be comparable to wildfire conditions (Fernandes and Cruz 2012), and outdoor experimental fires are often limited.

Nevertheless, the heat release rate estimated at laboratory scale is a good index to characterise fire hazard and it can be used to classify fuels (Babrauskas and Peacock 1992). The characterization of flammability of companion species might help managers to prioritise treatments to lower the cover of high flammable species in order to reduce mainly the vulnerability of cork oak forests to recurrent forest fires (Catry et al. 2012). Therefore, the aim of the present study is to significantly evaluate the flammability parameters, at laboratory scale, by means of mass loss calorimeters in some frequent species of conifers and oaks that mingle strongly in the oak forests in Algeria.

.

Materials and methods

Study site and Sampling

In the north of Algeria, the maquis is composed mainly of cork oak forests mixed with other hardwood and softwood species. For the purposes of the study, fuel samples were collected in a cork oak (*Quercus suber*L.) forest in the southern part of the mountains of Tlemcen (West of Algeria) (Fig. 1 left). The area is characterized by a sub-humid climate with 27 °C of average annual temperature and 500 mm of mean annual precipitation. The altitude varies between 1000 and 1282 m and the slope between 1.1 and 9.1%. In addition to *Quercus suber* as the main tree species, the following companion species (were considered: *Pinus halepensis* Mill., *Quercus ilex* L., *Quercus faginea* L., *Juniperus oxycedrus* L. and*Tetraclinis articulata* Vahl.). These species are frequent in cork oak forests and in the Mediterranean basin.

Fuel sampling was carried out during the fire season (September 2017) with the aim of assessing the effect of phenology on vegetation flammability and selecting low fuel moisture contents corresponding to high levels of fire hazard. Samples (approximately 500 g) of live

fine fuel (twigs Ø < 0.6 cm with foliage, according to Madrigal et al., (2009) were collected in five independent plots along one transect (34° 51′ 12.86″ N, 1° 21′ 07.99″ W) throughout the study area. In each plot, five trees and shrubs of each species were chosen at random. The samples were obtained with the aid of prune clippers and a telescopic saw.
Live fine fuel (approximately 500 gr) samples (twigs Ø <0.6 cm with foliage) were randomly collected from the upper, middle and lower part of the crown from different trees and shrubs, using prune clippers and a telescopic saw. It is wiser to record that all samples were placed into hermetic plastics bags and transported to laboratory in portable refrigerators within a few hours of the same day of collection. Once in the laboratory, one 100 g subsamples of each fine fuel sample were used to determine the fuel moisture content (FMC) by oven-drying the material in an oven at 100 ± 2°C during 24 h (until a constant weight was reached).

Experimental procedure
Indeed, 07 replicates were tested for each series in order to obtain at least 03 replicates which comply with repeatability criteria (Madrigal et al. 2009, 2013). Paired-samples were used in the experiment according to the methodology proposed by Madrigal et al (2013): one for the FMC determination using a moisture analyzer Computrac MAX ® 2000XL (Arizon Instrument LLC), the other for flammability tests (Mass Loss Calorimeter, FTT®) (Fig 1. right).In order to compare and classify the six species of the maquis and to thorough representation of the four flammability components sensu White and Zipperer (2010), the following parameters were measured: Time-to-ignition (TTI, s) for ignitability; Effective Heat of Combustion (AEHC, MJ/kg) for sustainability; Peak Heat Release Rate (PHRR, kW/m2) for combustibility; and Residual Mass Fraction (RMF, %) for consumability.

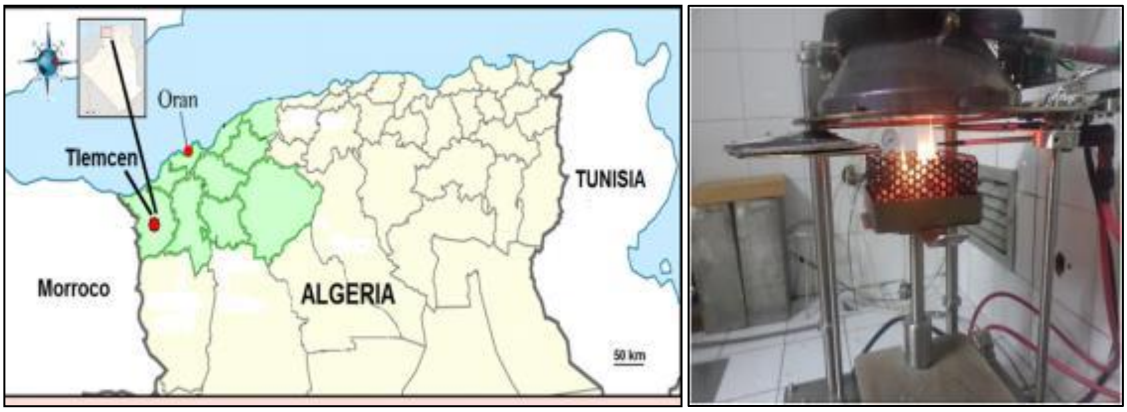

Figure 1. Left: Location of the study area Right: Flammability test in the Mass Loss Calorimete

Data analysis
Fuel moisture of fresh fuels (FMC) and flammability parameters (TTI, AEHC, PHRR, RMF) were compared by species using one-way ANOVA (n=30). Dunnest test was used to classify the forest fuel samples. SPSS.21® Software was employed to develop ANOVAs and to generate flammability classifications. The effect of FMC on flammability parameters was evaluated using a Pearson non-parametric correlation matrix.

Results and discussion

The results in the table show a marked variation between the averages recorded for the five parameters considered, a coefficient of variation varying between 17.66% (FMC) and 69.82% (ITT). Indeed, one may say that the ignitability under a heat source of 50 kW /m^2 varies from one species to another ($F = 49.36$, $p <0.000$). *Q. faginea* records the shortest time for ignition of the flame (12.42s) that is, this species has a high flammability potential. The minimum and maximum reached respectively vary from 6s to 19s respectively. On the other hand, Berber's thuya induces the slowest time (100.85s), with a minimum of 79s and a maximum of 122s. It is therefore the least flammable species.

Table 1. Measurements of the flammability parameters of the three species of oaks and conifers

Paramètres / Especes	FMC (%)	ITT (s)	PHRR (kW/m2)	AEHC (MJ/kg)	RMF (%)
J.oxycedrus	60,714(3,35)	46,85(18,56)	190,72(14,17)	10,22(2,52)	2,49(0,34)
P.halepensis	98,00(10,58)	89,57(21,29)	137,20(28,32)	7,42(2,92)	2,82(0,18)
T.articulata	71,42(71,42)	108,14(9,35)	128,67(89,53)	11,47(1,77)	3,55(0,30)
Q. suber	76,57(82,57)	28,14(12,79)	89,88(35,61)	7,52(2,50)	2,98(0,69)
Q. ilex	68,85(2,67)	31,85(11,92)	109,07(63,96)	8,60(1,74)	3,48(0,60)
Q.faginea	82,57(5.7)	12,42(4,57)	80,94(10,35)	4,45(1,61)	5,45(1,36)
Total	76,35(6,26)	52,83(37,33)	122,75(58,87)	8,28(3,08)	3,46(1,17)

As far as the Peak Heat Release Rate (PHRR, kW/m^2) is concerned, the variations are also marked between species ($F = 16.61$, $p < 0.000$). *Q. faginea* emits low heat among the six species, an average of 80.94 kW/m^2 with a minimum of 75.78kW/m^2 and 95.86kW/m^2. However, *J.oxycedrus* has the highest heat intensity, averaging 190.72kW/m^2, with a minimum of 160.71kW/m2 and a maximum of 199.60kW/m^2. With regard to durability measurements, Average Effective Heat of Combustion (AEHC, MJ / kg) records a very significant difference (($F = 8.50$, $p < 0.000$) Q. *faginea* is the weakest (4, 45 MJ / kg), with a minimum of 3.20 MJ/kg and a maximum of 7.20 MJ/kg, while *T. articiculata* records the highest values, an average of 11.47 MJ /kg, with a minimum of 9.60 MJ/kg, and a maximum of 14.30 MJ/kg.

Lastly, for the consumability measures, the differences are also detected (= 41.83, $p < 0.000$). *J.oxycedrus* induces the highest proportion of the residual mass among the six species, an average of 2.49%. In contrast *Q. faginea* holds the highest values (5.45%)

Effect of FMC on Flammability Parameters

The FMC was different among species collected during the same days (Fig.2). *P. halepensis* showed a FMC significantly higher than other tree species like *Quercus* (*Q.faginea, Q. ilex and Q. suber*) and *T. articulata*. Understory *J. oxycedrus.* presented similar FMC than *Quercus* spp.and *T. articulata* species.

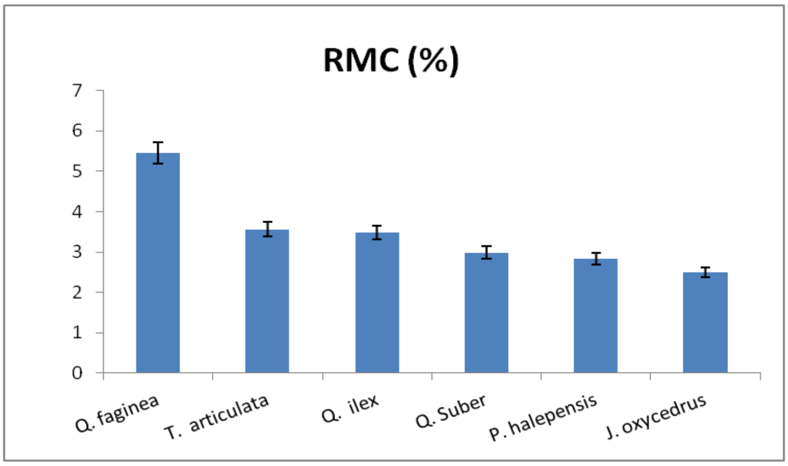

Figure 2. Fuel Moisture content (%) of selected species. Vertical bars show standard errors.

The effect of FMC on flammability parameters was evaluated using a correlation matrix. Surprisingly FMC did not show a significant correlation with TTI (ignitability) and RMF (consumability). A negative correlation was observed with PHRR (combustibility) ($p<0.01$) and with AEHC (sustainability) ($p<0.01$) (Table 2 and Fig.3).

Table 2. Correlation matrix (Pearson non-parametric correlation) for analyzed variables (*90% significance, **95% significance). Data (N = 42) correspond to 6 studied species (*Pinus halepensis*, *Juniperus oxycedrus*, *Tetraclinis articulata*, *Quercusilex.*, *Quercus faginea*, and *Quercus suber)*

	FMC	ITT	PHRR	AEHC	RMF
FMC	1,00	-0,15	-0,52**	-0,31**	0,13
ITT		1,000	0,39*	0,48**	-0,35*
PHRR			1,00	0,56**	-0,39**
AEHC				1,00	-0,34*
RMF					1,00

FMC fuel moisture content, TTI time to ignition, PHRR peak heat release rate, AEHC average effective heat of combustion, RMF residual mass fraction

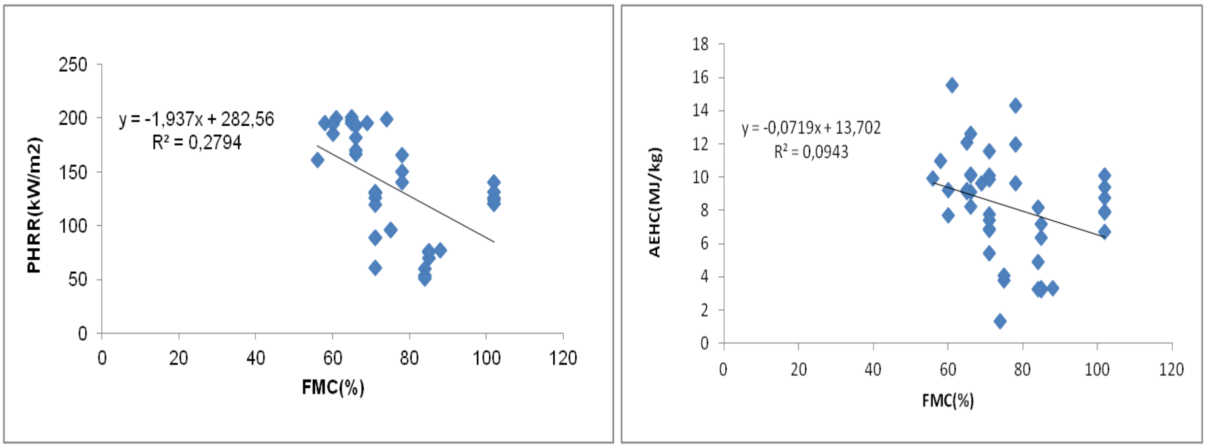

Figure 3. Correlation between Fuel Moisture Content (FMC, %) with (a) Peak Heat Release Rate (PHRR) and (b) Average Effective Heat of Combustion.

1.1.*Flammability of Cork Oak Forest Species*

Figure 4 reflects the comparison among analysed flammability variables for selected species. *Q. faginea* presented higher ignitability (lower time-to-ignition, fig.4a), lower combustibility (PHRR, fig.4b) and sustainability (AEHC, fig.4c) and higher consumability (RMF, fig.4d) than most of studied species. Therefore, *A. articulata* could be considered the lowest flammable of the series (fig.4 b).

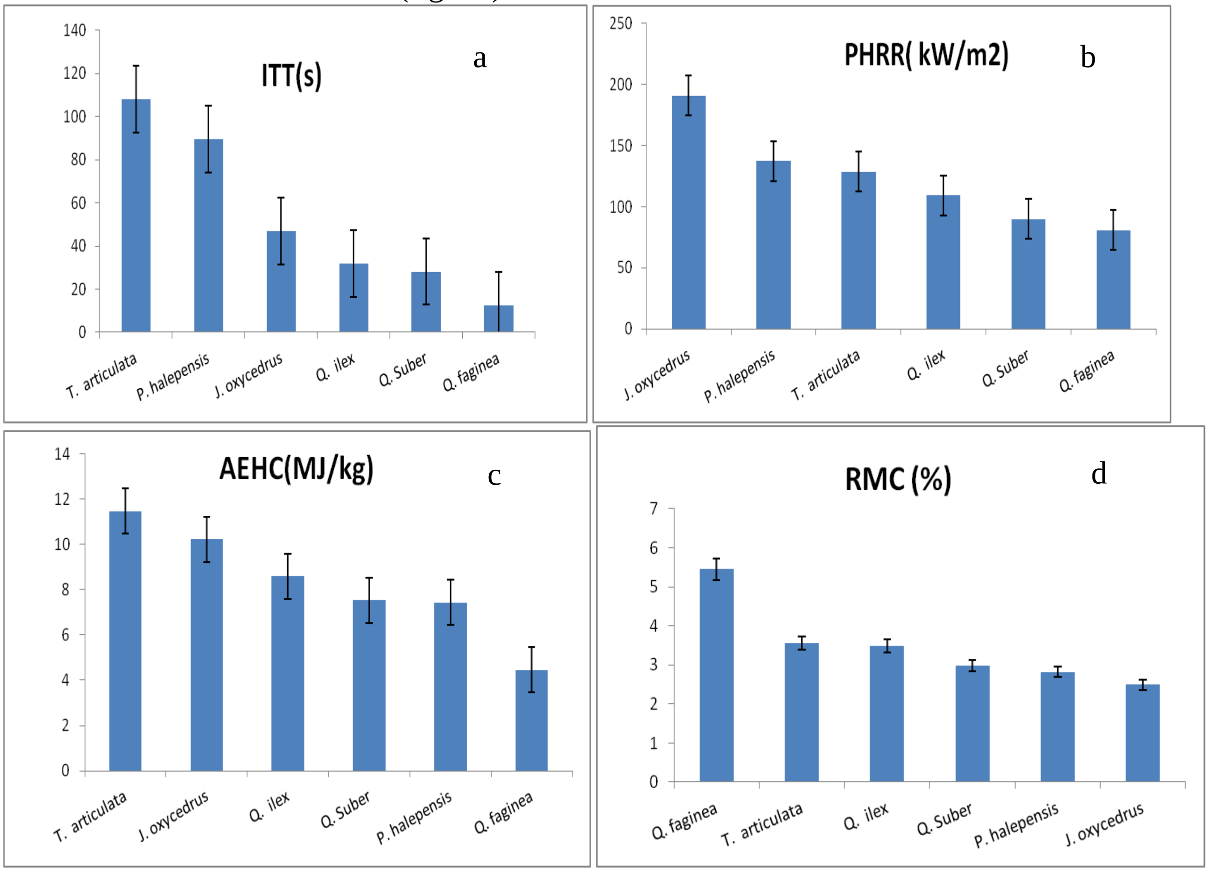

Figure 4. One-way ANOVA for selected flammability parameters (a) Time-to-ignition, TTI (b) Peak Heat Release Rate, PHRR (c) Average Effective Heat of Combustion, AEHC (d) Residual Mass Fraction (%). Vertical bars show average and standard errors. Different letters show significant differences ($p<0.001$).The flammability variables determined in the fresh samples were compared. The Dunnett test makes it possible to classify the species in homogeneous groups in relation to their respective parameters (Table 5).

Typically, a forest stand consists of various species possessing anatomical and physiological structures, very adapted to the conditions of the environment and to local ecological conditions (climate, soil and altitude). In the face of forest fire, none of these species is non-flammable, the ubiquitous flammability is hierarchized rather between a precipitated or delayed flammability in which the researchers evoke implicitly strongly, moderately or weakly flammable species. The water content of these trees (FMC or Fuel moisture content) is the main catalyst for flammability (Valette, 1990, Dimitrakopoulos & Mitsopoulos, 2006, Madrigal et al., 2009). The fire season in north Algeria extends from May to October. Such a period is characterized by the lack of rain and average daily temperature is higher than 30°C. Hence, a condition which generates water stress in the vegetation.

These two parameters, which jointly regulate soil water balance and evapotranspiration, are intercepted differently by forest trees. This implies that coniferous and broadleaved trees implement differentiated physiological regulations to avoid drought (Dimitrakopoulos and Mitsopoulos, 2006). Contrary to most previous studies, FMC did not have a significant effect on TTI (ignitability) or RMF (consumability) ($p > 0.5$). The moisture content of the fuel (FMC> 50%) generates high variability in the TTI (between 60,71% and 98%) and RMF (between 2,49 and 5.45%) values and, therefore, it was not possible to identify differences between species. Indeed, the effect of FMC of live fuels on forest fire behaviour at high radiant heat flux is controversial (Madrigal et al. 2013). Some authors consider that under such circumstances, the effect of the feedback from the fire and accumulation of VOCs may be stronger than the FMC (Viegas and Simeoni, 2011).

M 'Hamed et al. (2011) confirms this is probably due to the presence of high content of extractives and volatilized aromatic essential oils in the north-African foliage fuels specially in cork oak forests. Emission of VOCs is favored by evaporation of water due to the transportation of such compounds by water molecules during the evaporation process (Chetehouna et al., 2009). However, the results of the tests showed a considerable correlation between FMC and PHRR (combustibility, $r = -0.52$, $p < 0.05$) and between FMC and AEHC (sustainability, $r = -0.31$, $p < 0.05$) (Fig. 3). Thus, as the water content (FMC) decreased, the speed of combustion (PHRR) and heat release (AEHC) increased. Indeed, these findings show the importance of these variables in describing the combustion process (Babrauskas and Peacock 1992) and the possible involvement of VOCs in accelerating combustion (Viegas and Simeoni 2011, Chetehouna et al. 2014).

Oak species presented low values of the four flammability parameters (high ignitability but lowcombustibility, sustainability and consumability). The fuel moisture content of Quercus spp. is lower than that of other more flammable species (e.g. *P. halepensis*). Despite being highly flammable (due to its high surface area-to-volume ratio -Valette 2007- and low FMC in leaves), *Quercus* spp. do not store VOCs (Peñuelas and Llusia 2003) and have been described as less flammable than conifers (Pausas et al. 2015). This group of species can be considered as intermediate between "non-flammable" and "hot-flammable" under the new evolutionary concept defined by Pausas et al. (2017). Conifers species forms the most flammable group: *J. oxycedrus, T. articulata,* , *P. halepensis,* are phenologically and physiologically very similar and can be considered "hot flammable" under the new

evolutionary concept defined by Pausas et al. (2017). They are characterised by a very poorly lignified leaf, generally growing in southern areas on limestone and rockyground.
Juniperus oxycedrus is recognised as a highly flammable species in the Mediterranean region (Madrigal et al. 2011) because of its very high surfacearea-to-volume ratio and low FMC during the summer (Valette 1990; Elvira and Hernando 1989). In addition, *T. articulata and J. oxycedrus* both belong to the Cupressaceae fam.,in which it is characterised by the accumulation of VOCs (Della Rocca et al. 2015). *P. halepensis* is more flammable than the other species. The resin and essential oil (terpenoids) contents of*P. halepensis* tend to be very high, making these species extremely flammable (Dimitrakopoulos et al. 2013). As an indication, Aleppo pine forests cover more than 800 000 ha in Algeria and alone account for 1/3 of all burned areas in the Mediterranean region (Leone, 1999).
A proposed classification of some companion species of cork oak forest could potentially be used as predictors of the actual risk of fire in these stands. A recent proposal (Molina et al. 2017) shows that flammability rankings can improve fire risk indexes. In the same line of tought, Fares et al. (2017) stated that the use of flammability classifications, including the natural dynamics of live fuels might enhance fire risk indexes in the Mediterranean region. The new flammability evolutionary concept proposed by Pausas et al. (2017) opens the possibility to study potential links between biology, physiology and flammability (Schwilk 2015) to improve flammability classifications.

Conclusion

The results indicate that the problematic of live forest fuel in the region of Tlemcen is the same in the others Mediterranean's country, especially in the North Africa. The abandonment and mismanagement of the maquis led to uncontrolled spatial distribution of *T. articulata* and *P. halepensis*. The findings suggest that mixed maquis with *P. halepensis and/or T. articulata* present a major risk to cork production in scenarios with increased fire occurrence. This recommends that the *P.halepensis* presents a very important risk to the cork oak forests where the phenomenon of dominance of softwoods is very marked. Depth knowledge on forest fuel in the Algerian cork oak forests requires sampling consisting covering large areas. The results dictate the need for future research to put important points such as the interaction between FMC in the fresh and dried fuel, volatile compound and radiant heat flux. This would facilitate the fire risk mapping, mainly for the already managed forests with known ecological association units.

Abstract

The paper shows the results of road network data analysis for associated compartments and forest categories in Forest Management Unit "Meštrevac" (the municipality of Foča, Entity of Republika Srpska, Bosnia and Herzegovina), performed in the GIS software package ArcMap 10.5. The real mean skidding distance is obtained as a product of the mean geometric skidding distance and correction factor. The correction factor is calculated as the average value of the correction factor by terrain slope and correction factor by relief areas. According to the current state, the entire road network is made up of roads with a macadam type of pavement. The total length of mentioned roads is 124,95 km. Due to the spatial position of certain sections that unilaterally open the forest area, the total length of the roads is taken into account with 79.31% of its length (99,10 km) and so openness of FMU "Meštrevac" has a value of 8.63 m/ha. From a total of 157 analyzed compartments, 41 of them are not opened with forest road network at all. The mean geometric skidding distance has value of 330.96 m. With the calculated correction factor of 1.48 in mind, the real mean skidding distance has value of 489.82 m. Based on characteristic cases of the spatial position of some sections in the road network, the criteria used to determine road network density are subsequently supplemented by the corresponding criteria.

Key words: *road density, openness, mean skidding distance, correction factor, GIS.*

Introduction

A well-built network of forest roads is the starting point for planning and implementing measures of care, cultivation and use of forest resources. Building a primary network of forest roads in the forests, regardless of the ownership structure, has a wider social significance, whether if the subject of the opening are private forests, spatially separated forest complexes of state forests or state forests in general (Đuka *et. al.*, 2017). According to Petković and Potočnik (2018), forest roads should be built in areas that are suitable to their construction, and suitability is determined by grading the terrain, habitat conditions and the existing network of forest roads, i.e. current openness. However, road construction is often limited due to the current needs, the most pressing technological and technical problems and financial possibility of a legal entity that manages the forest area.

The first step through which we can point out the basic drawbacks and lay the foundation for the future upgrading of the existing forest road infrastructure is to determine the road network density. Although Pentek (2011) states that road network density is a quantitative parameter that, besides the numerical data on the amount of road infrastructure on a certain surface, does not say anything about the quality of its spatial distribution. Using modern technologies (GPS devices and GIS software) and applying the criteria for determining road network density developed by Poršinsky *et al.* (2017), the entire job of recording and inventoring of roads is extremely easy and simplified. The efficiency of using GPS devices for recording the existing forest road network has been demonstrated by Potočnik *et. al.* (2009), stating that the use of GPS devices for the same time period allows even 6 shots more than classic way of recording. Within the GIS software platform, we can display the collected data in raster and vector form, then systematize them into the appropriate bases and perform multi-criteria analysis. As the positive correlation between openness and mean skidding distance is evident, according to Petković *et. al.* (2015) determining the mean skidding distance is imposed as one of the most important tasks especially in the process of forest openness planing. This is supported by the fact that the size of the mean skidding distance directly affects the unit labor costs in the 1st stage of timber assortments transport. According to Simić (2007: Kulušić, 1979), in total forestry production costs, the timber assortments transport costs account for as much as 60%. The modern approach to determining the mean skidding distance involves assisting the GIS platform and applying different methods within them. According to Pentek *et. al*. (2005); Danilović *et. al.* (2012, 2013); Danilović & Stojnić (2014); Petković *et. al.* (2015, 2017), the mean skidding distance is the product of the geometric mean skidding distance, which is determined using the raster method, grid point method, the buffer strips method (Enache *et. al.,* 2015) and the correction factor, determined on the basis of terrain relief characteristics and analytical methods (Petković *et. al*., 2015, 2017, Lotfalian *et. al*., 2011). The aim of this paper is to determine road network density and the mean skidding distance in the Forest Management Unit "Meštrevac" with the application of modern methods and techniques, with an overview of the advantages and disadvantages of the used methodology.

Material and Methods

The research is carried out at the FMU "Meštrevac", located in the southeastern part of the Republic of Srpska/Bosnia and Herzegovina, on the territory of the Municipality of Foča (Figure 1). This Forest Management Unit belongs to the Forest Management Area "Gornjedrinsko", which is managed by the Forest Enterprise "Maglić" Foča. It ranges from 18°54'22" E to 19°05'20" E and from 43°15'01" N to 43°27'22" N. The value of FMU "Meštrevac" area listed in Forest Management Plan is smaller by 155.50 hectares or 1.35% compared to GIS determined area (Table 1.). The terrain relief is typically mountainous (highest point - Ljubišnja 2238 m), with narrow canals and river canyons (Tara and Ćehotina). According to the Forest Management Plan, the total area of FMU "Meštrevac" is 11300.36 ha (IRPC, 2010). Cuting volume for ten-year period is 416,242 m^3 of wood, where 340,535 m^3 is from coniferous and 75,707 m^3 from deciduous trees (IRPC, 2010).

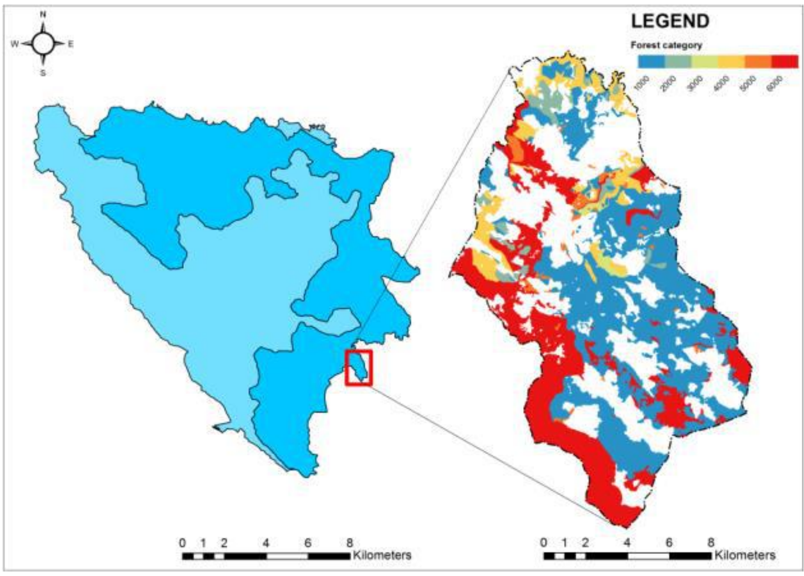

Figure 1. Geographical location and spatial distribution of forest categories in FMU "Meštrevac"

Table 1. Overview of Forest Management Unit "Meštrevac" area according to the forest categories

Forest category	**Area**		**Relative share**
	FMP	**GIS**	
	ha		**%**
1000 – High forests with natural regeneration	5980.74	5681.12	49.59
2000 – High degraded forests	334.71	501.38	4.38
3000 – Forest plantations	112.24	108.13	0.94
4000 – Coppice forests	1125.01	1084.38	9.47
5000 – Surfaces suitable for afforestation and forest management	149.65	324.57	2.83
6000 – Surfaces unsuitable for afforestation and forest management	3710.25	3755.83	32.79
TOTAL	**11300.36**	**11455.41**	**100**

Larger part of the primary forest road network is recorded by forestry engineers from FE "Maglić" using the GARMIN Oregon 600 GPS device, while the rest is recorded using the Garmin Etrex 10 GPS device by first author. The recording is performed by driving on a one way direction.
Transformation of recorded data from gpx format into shapefile format, suitable for processing in ArcMap 10.5 software package, is done using the DNR GPS software.
Correction of the spatial position of the recorded roads is made using a orthophoto image with resolution of 1 m.
Vector data (the boundary of the Forest Management Unit, compartments and forest categories) is obtained by digitizing forestry thematic maps of scale 1:25 000 from Public Forest Enterprise "Šume Republike Srpske".
The road network density is calculated using the expression (1):

$$R_d = \frac{L_r}{A_t} \quad (1)$$

Where is:
R_d - primary road network density (m/ha)
L_r – primary road network lenght (m)
A_t - total area (ha)

Calculation of road network density is done using criteria developed by Poršinsky *et. al*. (2017):

General criteria:
a) the road has an upper structure,
b) the road to a greater extent meets the essential minimum technical characteristics required for the transport of wood by truck,
v) there is no traffic signal on the road with a regulated axle load limit of less than 10 tonnes and a total load less than 26 tonnes,
g) wood can be skidded to the road, while forest vehicles will not move on non-forest soil (agricultural land, urbanized land, etc.).

Special (spatial) criteria:
1. forest, public or "unclassified road", or its particular section, which can be used for sustainable forest management, mainly for the loading of timber assortments, which, through its entire length, passes through the forest and/or forest land and which opens forest from two sides, is taken into account with all its length (100% of length),

2. forest, public or "unclassified road", or its particular section, which can be used for sustainable forest management, mainly for the loading of timber assortments, which through its entire length passes through the forest and/or forest land; and which opens the forest unilaterally, due to various restrictions, is taken into account with half of its length (50% of its length).
3. forest, public or "unclassified road", or its particular section, which can be used for sustainable forest management, mainly for the loading of timber assortments, passing along the the Forest Management Unit boundary (hereinafter: the border), or up to a maximum of 250 m from the boundary from its external or up to 125 m distance from the border on its inside, whose route generally follows the direction of the border, is taken into account with half of its length (50% of its length).
4. forest, public or "unclassified road", or its particular section, which can be used for sustainable forest management, mainly for the loading of timber assortments, which extends to the Forest Management Unit boundary (hereinafter: the border) at right angle approximately (90°±20°) and ends at the boundary, is taken into account with a length of 250 m. If the length of the mentioned section of the primary road network is less than 500 m, it shall be taken into account with half of its length (50% of length). If the same section does not end at the border but enters in road opened area, on it, within the mentioned border, other general and specific criteria for determining road network density are applied.
5. forest, public or "unclassified road", or its particular section, which can be used for sustainable forest management, mainly for the loading of timber assortments, which comes close to the Forest Management Unit boundary (hereinafter: the border) but which is the subject of forest opening by primary road network at approximately the right angle (90°±20°), but ends on the outside of the boundary, is taken into account with a length of 250 m, reduced by half the distance of its ending from the border.

Determination of the geometric mean skidding distance is carried out using the grid point method - G100 (Enache *et al*., 2015), with *Arctoolbox Fishnet* tool. Using this method, 8359 points are placed within the area of FMU "Meštrevac". The shortest distance from each point to the road network is calculated. Average value of these distances for/inside every single opened compartment is taken as its mean geometric skidding distance (2) (Đuka *et. al.*, 2017):

$$\bar{\mathrm{S}}_{\mathrm{g}} = \frac{\sum_{\mathrm{i=1}}^{\mathrm{n}} \mathrm{S}_{\mathrm{g_i}}}{n} \quad (2)$$

Where is:
$\bar{\mathrm{S}}_{\mathrm{g}}$- mean geometric skidding distance (m),
$\sum_{\mathrm{i=1}}^{\mathrm{n}} \mathrm{S}_{\mathrm{g_i}}$- the distance of all points within the compartment (m)
n – the number of uniformly distributed points over the compartment surface.

Using the *Arctoolbox Slope* tool, an slope analysis is performed with 25 m resolution Digital Elevation Model (EU-DEM v1.1) from the Copernicus program[17]. The resulting slope raster is classified into 5 categories with intervals: 0-15%, 16-30%, 31-45%, 46-60% and 61-140% (Figure 4). Summating the products of all 5 slope categories area relative share in investigated area and average correction factor for every single terrain slope category, a correction factor is obtained (Petković *et. al*., 2017, according to Sokolović & Bajrić 2013).

With additional analysis of the Digital Elevation Model we determined relative participation of relief categories in the FMU "Meštrevac" investigated area, where, acording to Petković *et*

[17] **Copernicus** is the European Union's Earth observation programme coordinated and managed by the European Commission in partnership with the European Space Agency (ESA), the EU Member States and EU Agencies.

al. (2015: Bertović 1999), areas located up to 200 m above sea level are characterized as lowlands, from 200 to 500 m as hilly area, from 500 to 1000 m as low mountains, from 1000 to 1500 m as medium high mountains and from 1500 to 2000 m as high mountains. Pentek *et. al.* (2005: Segebaden 1964, 1969 and Abegg 1978) states that the correction factor ranges from 1.5 to 1.65, in average 1.58 for mountain areas in Sweden and Switzerland.

The overall geometric mean transport distance correction factor is determined as the average value of the terrain slope correction factor and correction factor for the relief areas (Petković *et al.,* 2015).

The area of all open compartments in FMU "Meštrevac" including buffer whose border reaches up to 250 m from the boundary of open compartments is taken as investigated area.

The real mean skidding distance is calculated as the product of the mean geometric skidding distance and the overall correction factor (3).

$$\overline{\mathrm{S}}_d = \mathrm{S_g} * f_k \quad (3)$$

Where are:
$\overline{\mathrm{S}}_d$ – real mean skidding distance (m),
$\mathrm{S_g}$- mean geometric skidding distance (m),
f_k – correction factor.

Results and Discussion

According to the current state, the entire road network is made up of roads with a macadam type of pavement. The total length of the roads that open FMU "Meštrevac" (Figure 3) is 124.95 km. Due to the spatial position of certain sections that unilaterally open the forest area, the total length of the roads is taken into account with 79.31% of its length (99.10 km) and so openness of FMU "Meštrevac" has a value of 8.63 m/ha. In compartments with an openness greater than 10 m/ha (Figure 5), high forests with natural regeneration occupy 54.52% of the area. Moreover, the largest part of the forest road network has been built within the area of high forests with natural regeneration (Table 2). This result unequivocally indicates that the construction of roads in FMU "Meštrevac" is in direct dependence on planned revenues from exploitation of forest areas that are the subject of the opening. Although the openness of forest plantations and surfaces suitable for afforestation and management is at a satisfactory level (Table 2), the current state is undoubtedly a consequence of the relatively small share of the mentioned categories area in FMU "Meštrevac" (Table 1) and proximity to existing roads that open high forests with natural regeneration. In accordance with the silvicultural and economic potential, perspective for opening coppice forests and areas unsuitable for management in the past did not exist, so their openness today is at an extremely low level. Since modern approach to forest management implies respecting the principles of polyfunctionality, this area will be the subject of opening in the future, as evidenced by the construction of the road along the Tara River canyon for the purpose of tourism development.
Most "well-opened" compartments (30) are opened in the range of 10.01–15.00 m/ha (Figure 2). For mountain areas in Croatia, as is the area of FMU "Meštrevac", the minimum recommended openness is 15 m/ha (Pentek *et al.,* 2011) or 20 m/ha (Hodić & Jurišić 2011). In Austria, whose productive forests are mainly located in the mountainous area, openness is at a high level with 45 m/ha (Findeis, 2016). Compared to the above, the openness of FMU "Meštrevac" cannot be considered satisfactory.

Table 2. Average density and length of forest road network by forest category in FMU "Meštrevac'

Forest category	Primary road network	Road network density
	m	m/ha
1000	68298.27	11.81
2000	2062.83	4.48
3000	2079.71	20.71
4000	3439.59	3.23
5000	5329.46	20.34
6000	26201.51	6.93

By analyzing the DEM it is found that the investigated area in FMU "Meštrevac" consists of 0.28% of hilly and 99.72% of mountainous areas (low mountains: 22.01%, medium high mountains: 58.32% and high mountains: 19.38%). Since the participation of hilly areas is negligible, the area of FMU "Meštrevac" can be fully defined as mountainous and as such it has a correction coefficient of 1.58. Taking into account that the total correction factor is equal to the average value of the correction factor by terrain slope (Table 3) and correction factor by relief areas, the total correction factor has a value of 1.48.

Table 3. Calculated corection factor acording to terrain slope in FMU "Meštrevac"

Slope category	Corection factor	Relative share in total area (%)	Total
0 - 15	1.1035	25.11	0.28
15.01 - 30	1.2305	33.80	0.41
30.01 - 45	1.3625	19.00	0.26
45.01 - 60	1.5815	11.41	0.18
60.01 - 140	2.3265	10.68	0.25
Total	/	**100**	**1.38**

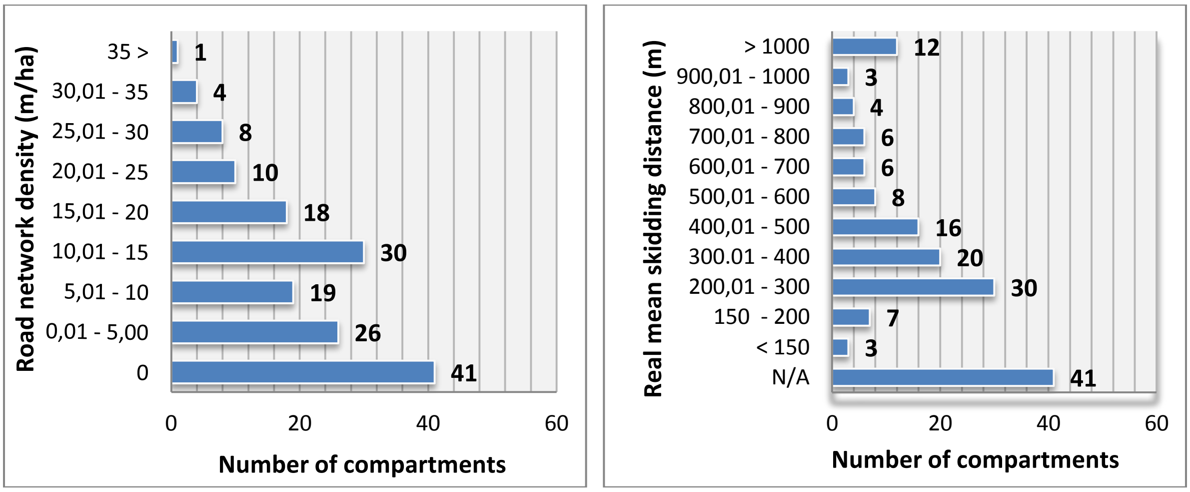

Figure 2. Numerous distribution of compartments according to the classes of openness (left) and real mean skidding distance (right) in FMU "Meštrevac"

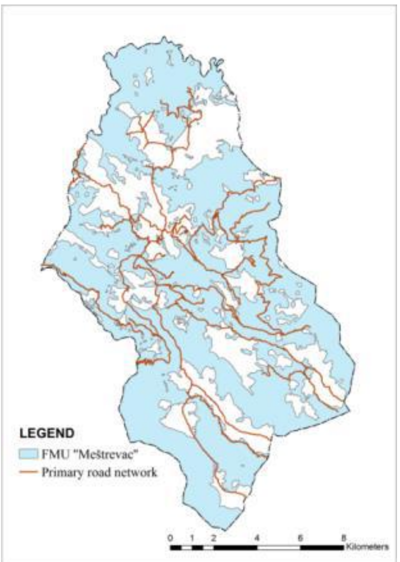
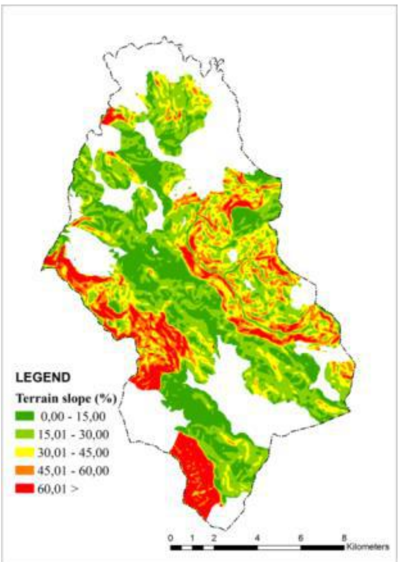
The mean geometric skidding distance in FMU "Meštrevac" is calculated with value of 330.96 m. According to the calculated correction factor for FMU "Meštrevac", the real mean skidding distance will be 489.82 m. The mean skidding distance obtained by this methodology is often approximate, but satisfactory to the level of strategic planning. Figure 2 shows the numerical distribution of open compartments according to the classes of the real mean skidding distance, where we can see that the largest number of compartments is located whitin range of 200.01-300.00 m. The spatial distribution of these compartments is shown in Figure 6.





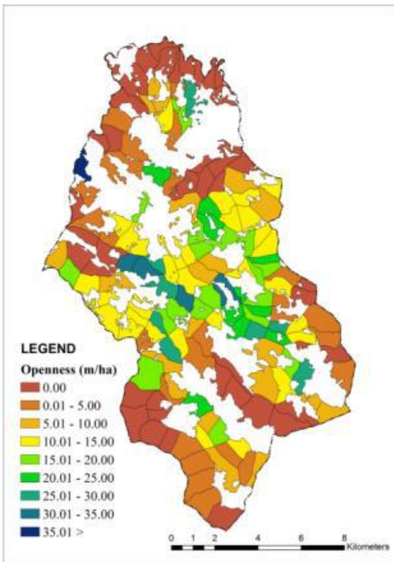


Figure 3. Primary forest road network in FMU "Meštrevac" (left),
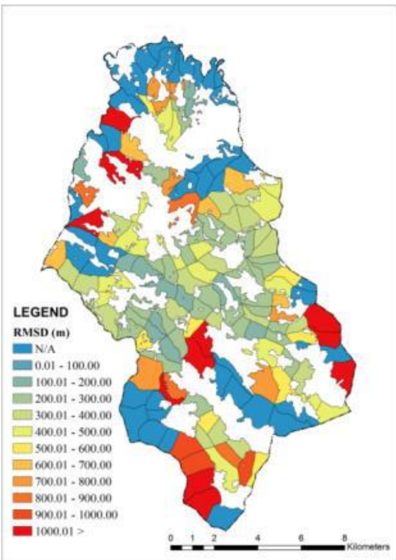
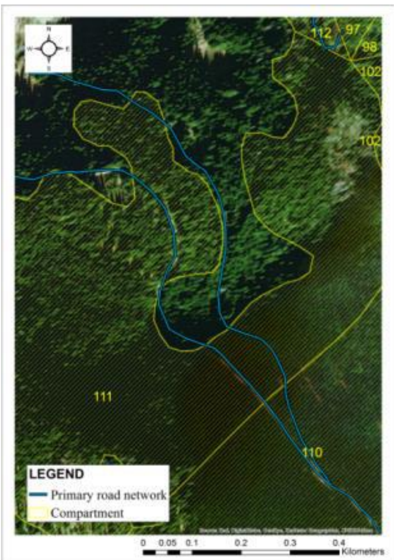
Figure 4. Terrain slope in FMU "Meštrevac" (middle)
Figure 5. Road network density by compartments in FMU "Meštrevac" (right),





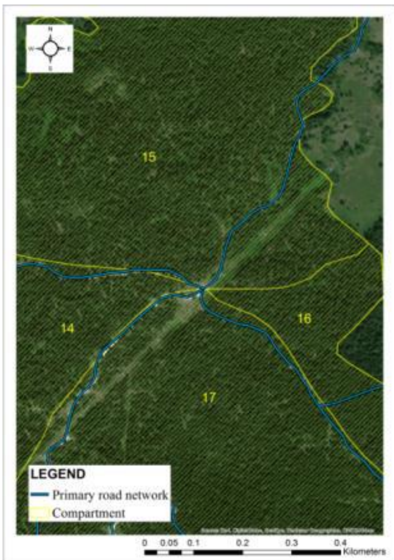


Figure 6. Real mean skidding distance by compartments in FMU "Meštrevac" (left)
Figure 7. Characteristic case of road spatial position in FMU "Meštrevac" – example 1 (middle)
Figure 8. Characteristic case of road spatial position in FMU "Meštrevac" – example 2 (right)

Conclusions

Numerical values of openness obtained according to the criteria developed by Poršinsky *et al.* (2017) at the same time represent an assessment of the spatial distribution of the primary road network, since the spatial position of the roads defines the numerical value that is taken into account. However, as mentioned by the authors, possible cases in operational/practical forestry that can be encountered in determining of primary forest road network density, are almost countless. In order to complement the mentioned criteria, it is necessary to analyze as many areas as possible with their typical field conditions. Its the only way that undefined cases can be spotted, processed and channeled into a new criterion.

According to characteristic cases from FMU "Meštrevac" section of special criteria should be supplemented with:

1. The forest, public or "unclassified road", or its particular section which, due to its characteristics, is taken into the account for openness calculating under paragraphs (1), (2)

and (3), which is located nearby, according to the above criteria relevant, other forest, public or "unclassified road" so that its route closely follows its direction is taken into calculation with (Figure 7):

a) 50% of the length: 225 ≤ 250 m from another forest, public or unclassified road,
b) 45% of the length: 200 ≤ 225 m from other forest, public or non-classified roads,
c) 40% of the length: 175 ≤ 200 m from other forest, public or unclassified roads,
d) 35% of the length: 150 ≤ 175 m from other forest, public or non-classified roads,
e) 30% of the length: 125 ≤ 150 m from another forest, public or unclassified road,
f) 25% of the length: 100 ≤ 125 m from other forest, public or non-classified roads,
g) 20% of the length: 75 ≤ 100 m from other forest, public or non-classified roads,
h) 15% of the length: 50 ≤ 75 m from other forest, public or unclassified roads,
i) 10% of the length: 25 ≤ 50 m from other forest, public or unclassified roads,
j) 5% of the length: <25 m from another forest, public or unclassified road.

2. Forest, public or non-classified road, or its particular section, which can be used for sustainable forest management, mainly for the loading of timber assortments, which is connected to another forest, public or non-classified road at approximately right angle (90°±20°), is taken into account with a whole length but reduced by 250 m, while the other criteria for determination of forest road netwerk density are applied to the reduced length (Figure 8).

The determination of the mean skidding distance in this paper carries certain characteristics. Unlike Petković *et al.* (2015, 2017), which analyzed terrain slope on the entire area of FMU, in the case of FMU "Meštrevac" terrain slope is analyzed only on areas where by using Poršinsky *et al.* (2017) general and special criteria a certain level of openness is determined. In this way, only those areas where theoretically timber assortments could be transported with transportation means in first stage of timber assortments transportation are taken into account, assuming that transportation of timber assortments cannot be done in unopened compartments. The value of the mean skidding distance obtained in this way is not burdened by analyzes of those areas where transportation of timber assortments will not be carried out, i.e. in those areas that often cannot be opened by the primary and secondary forest road networks, and the results thus obtained can be considered more precise.

Abstract

In this paper, the diameter increment of European silver fir is analysed on the basis of bioindication of the vitality of trees and forest stands. The research is accomplished by examining characteristics of the annual diametre increment on Mt Borja for the period of 50 years. The required data are collected on five trial plots in various stands, with four of them placed in mixed stands of fir and beech, and one being an exclusive fir stand. A total of 75 trees of the first, second, and third biological sites respectively are cored. In order to minimise the influence of age, to better detect the reaction of trees to exogenous factors on the radial growth and the evaluation of vitality of trees and stands, indexes of the tree rings width are calculated. The average values of the tree ring width are obtained through levelling in the ANTEVS programme (using the so-called smoothing cubic spline). Summarising the explored stands, it can be concluded that their vitality is solid and that possible devitalisation in the future can be prevented by the application of appropriate silviculture measures.

Keywords: *European silver fir, diameter increment, vitality, bioindication, Borja*

Introduction

In all European countries, modern-day forestry has been confronted with the challenge of securing permanent efficiency of forest ecosystems with a view to fulfilling their basic economic and ecological functions. This primarily means that it is necessary to maintain the stability of forests and their key features, such as biological diversity, renewability, production of biomass etc. Thus, defining the optimal structure of forest stands and an objective assessment of their current condition represent an important prerequisite for viable forest management in terms of economy and ecology (Vučković *et al*., 2004).

With regard to Bosnia and Herzegovina, the fir is usually found in mixed beech and fir, that is, beech, fir, and spruce forests, extremely rarely in exclusive fir forests, covering more than 50% of total high forests (Ballian and Halilović, 2016). The fir is the most common conifer in Bosnia and Herzegovina. The surface area of conifer forests and mixed conifer/broadleave forests, with regard to fir, beech, and spruce, is 599, 000 ha or 28% of productive forest area (Čabaravdić *et al*., 2016).

The examination of trees affected by drying points to the fact that their increment may show a long-term tendency of deviating from the 'normal' trend and that the process of losing vitality may begin much before there are visual symptoms evident (Vučković and Stamenković, 2000; Vučković *et al*., 2008).

Increment can be considered a reliable bioindicator of the tree vitality and the ecological conditions in which the tree grew and a parametre for forecast, that is, prediction of devitalisation and dying-off of trees in future. Consequently, the increment of dendromass can be used as a reliable indicator of general functionality of forest ecosystems. Numerous research have shown that changes in increment and its deviations from typical trends represent a bioindicator of tree and stand vitality. The changes in increment may point to the beginning of destructive processes even before there are visual symptoms of tree devitalisation, where the drying featuring the latter symptoms is only the final phase of a devitalisation process, which may pass unnoticed for decades. The monitoring of diameter increment of trees and stands and the forecast of their trend may enable a timely discovery of devitalisation, as well as minimising a possible damage in the period prior to visual symptoms of drying (Fritts, 1976; Prpić *et al*., 1994; Vučković *et al*., 1998, Bigler and Bugman, 2003, 2004; Vučković *et al*., 2004, 2005; Dukić and Maunaga, 2007, 2009; Stajić, 2010, Stajić *et al*., 2017 itd.).

Given the aforementioned, the examination of fir diameter increment on Mt Borja should contribute the applicability of increment analysis with a view to timely detecting of negative processes and decrease in tree and stand vitality, that is, detecting these processes prior to the occurrence of visual symptoms of drying to the extent that unanimously points to the decay of stands. Apart from scientific contribution, the results gained can be applied in forest management of pure stands of fir and mixed stands of fir and beech on Mt Borja.

Material and Methods

The researched area is Mt Borja, located in the northern part of Central Bosnia, between the rivers of Velika and Mala Usora, with its highest peak, Velika Runjavica (1,077m) dominating its north-west part. In most cases, the mountain is covered by mixed stands of fir and beech, with occasional occurrence of pure stands of fir (uneven-aged stands). Within the project of comprehensive research of increment of European silver fir, there have been 15 trial plots (50m x 50m) of pure stands of fir and mixed stands of fir and beech. Out of these, there are 5 trial plots (TP) selected (Trial plots: 1, 3, 5, 10 and 13) characterised by various conditions in terms of their habitat and stands. With regard to the aforementioned, the data necessary for bioindication vitality, based on the characteristics of diameter increment. The trial plots 1, 3, and 10 are set up in the *Rusco hypoglossi-Abietetum* association Brujić 2004, and the plots 5 and 13 in the *Galio rotundifolii-Abietetum* association Wraber 1959. On these plots, all trees with the diameter at breast height (dbh) larger than 5 cm have been subjected to the measurement of basic elements of growth: dbh, tree height (h), and the crown projection area, as well as biological position and tree vitality. Based on the extent to which their canopies are developed and the extent of light availability/ accessability, the trees are distributed into three biological classes (position), according to Bunuševac (1951): dominant trees (First biological position, Kraft 1 and 2), codominant trees (Second biological position, Kraft 3 and 4a), and overtopped trees (Third biological position, Kraft 4b and 5). With regard to vitality, all fir trees are classified in three categories (Innes, 1990): good vitality (1), medium vitality (2), and poor vitality (3).

As far as the researched stands in the aforementioned plots are concerned, the number of trees per ha ranges from 392 to 732 (560 on average), that is, the number of fir trees ranges from 200 to 604 (440 on average). With regard to the fir, the quadratic mean diameter is within the 22.8 – 39.3 cm range. When the stand basal area is concerned, it ranges from 24.9 to 35.1 m^2 ha^{-1}, with the volume of dendromass in the stands featuring the interval from 273.7 to 710.1 m^3 ha^{-1}.

On each trial plot, 5 trees from the first, 5 trees from the second, and 5 trees from the third biological position are drilled using Pressler increment borer for extracting long wood cores. The samples (wood core) are sent to a laboratory, placed and glued to guttered wooden supports, and then sanded down using sandpaper. The samples processed are scanned with a high-performance scanner (Epson Perfection V30 Photo). The measurement of ring width is performed by means of the CooRecorder 7.6 and CDendro 7.6 software respectively. With a view to removing, that is, minimising the influence of age on the increment trend, and in order to better detect the reaction of trees to exogenous factors on the radial growth and the evaluation of vitality of trees and stands, the following indexes of the tree rings width are calculated:

$I_r = \frac{i_r}{\hat{i}_r}$, I_r - ring width index, i_r - actual ring width , and $\hat{i}_r$ - estimated ring width.

The average values of the tree ring width are obtained through levelling in the ANTEVS programme (Rayburn and Vollmer, 2013; Vollmer, 2016), using the so-called smoothing cubic spline, thus providing estimated ring width values. Spline is a special function defined section by section over a polynome, so that it levels the connection between n spots defined in the Cartesian co-ordinate system (Pretzsch, 2009).

Results and Discussion

Table 1 shows the elements of growth of the trees encompassed by the analysis of diameter increment, with regard to their respective biological positions. According to this parametre, the arithmetic means of the diametres ranges from 11.7 cm to 43.1 cm, and of the heights from 9.7 to 28.5 m.

Table 1. Characteristics of the analyzed trees

Biological positions	Number of trees	dbh (cm)		h (m)		Crown projection area (m^2)	Vitality
		Means	Std. Dev.	Means	Std. Dev.		
I	25	43.1	8.7	28.5	3.5	13.5	1.2
II	25	22.6	6.2	18.6	3.5	9.2	2.3
III	25	11.7	3.0	9.7	2.3	3.8	2.7
All	75	25.8	14.6	18.9	8.4	13.6	2.1

The series of tree increment rings, with reference to the past 50 years (1965 - 2014) are divided by the levelled values (using the so-called smoothing cubic spline) by biological positions, resulting in the ring width indexes that enable the identification of the trees with hidden symptoms of devitalisation, that is, the trees that may feature vitality loss and be affected by drying processes. The trees that, over the period monitored, have displayed a significant decrease of the index, where this value has constantly been under 1 for the minimum of past 15 years, are marked as the trees with hidden symptoms of devitalisation.

Figure 1 shows the relation of the ring width index of a vital tree (tree number 150) and that of a tree with hidden symptoms of devitalisation (tree number 149) on trial plot 1. The trees are of nearly matching dimensions, with the former measuring 49.5 cm in diameter and 30.2 m in height, whereas the measures of the latter are 45.5 cm and 29.2 m respectively. According to Vučković et al. (2005), trees with a small ring width do not have enough capacity for transporting water and nutrients, which, in case of dominant trees, due to the extent to which their crown are developed and their great 'transporting distance', often leads to the disbalance between the intake and consumption of water, that is, to devitalisation and dying. Figure 2 shows the ring width indexes of the trees of the second biological position with hidden symptoms devitalisation.

There are analyses conducted of the differences between the vital trees and the ones with hidden symptoms of devitalisation in terms of dbh, height, crown projection area, and vitality by means of the t-test and F-test. The results show that, in relation to biological positions, there are no statistically significant differences between the two groups with respect to the parametres observed.

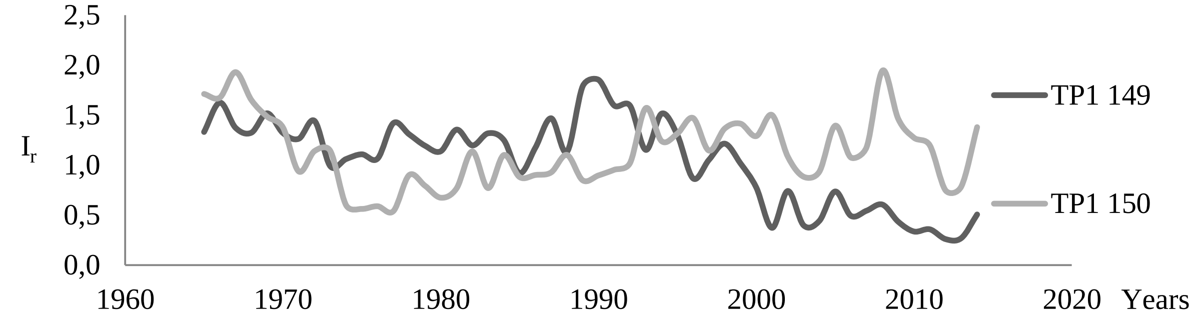

Figure 1. Vital trees (tree number 150) and tree with hidden symptoms of devitalisation (tree number 149)

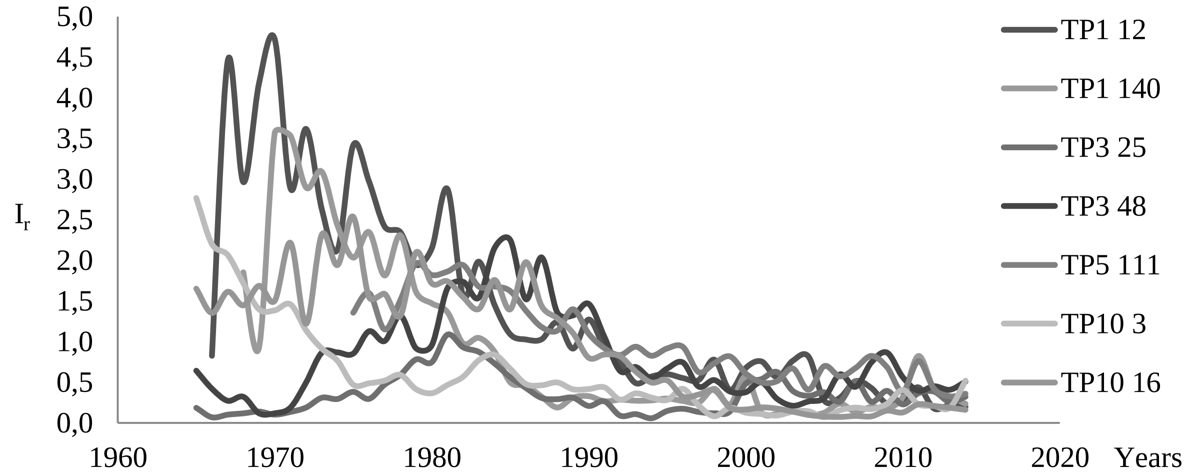

Figure 2. Ring width indexes of trees of second biological positions with hidden symptoms of devitalisation

Table 2 shows the respective share of the vital trees and the trees with hidden symptoms of devitalisation by trial plots and by biological classes. When dominant trees are concerned, the largest share of trees with hidden symptoms of devitalisation is found on trial plot 5, whereas the least share refers to trial plots of 3 and 13, where there are no such trees. In total, with regard to the researched stands, the share of dominant trees with hidden symptoms of devitalisation is 28%. Dukić and Maunaga (2009) applied the same method while researching on mature stands of sessile oak, and their results showed the share of dominant trees with hidden symptoms of devitalisation within the 31-35% range.

As far as codominant trees are considered, the largest share of trees with hidden symptoms of devitalisation is found on trial plots of 1, 3, and 10. Finally, with overtopped trees, the largest share of the trees with hidden sympotms of devitalisation is found on trial plots of 3 and 13.

Table 2. Share of vital trees and trees with hidden symptoms of devitalisation

Trial plots	First biological position		Second biological position		Third biological position	
	vital	devitalised	vital	devitalised	vital	devitalised
	(%)					
1	80	20	60	40	100	0
3	100	0	60	40	60	40
5	20	80	80	20	80	20
10	60	40	60	40	80	20
13	100	0	100	0	60	40
All	72	28	72	28	76	24

On the five trial plots researched, the number of fir trees per ha determined is 440 (206, 104, and 130 trees of the first, second, and third biological position respectively), that is, 560 with beech trees. Taking the aforementioned numbers and established shares as the starting point, there are 58, 29, and 31 trees of the first, second, and third biological position respectively with hidden symptoms of devitalisation. In total, the share of trees with hidden symptoms of devitalisation is 21%. In addition, we should take into consideration the fact that trends of diameter increment, which point to vitality loss in some trees, may, in fact, be the consequence of a somewhat less favourable position of the tree in question within its respective stand, due to a greater amount of shade provided by neighbouring trees, that is, due to increased competition between the trees in a stand, which becomes more pronounced as the trees progress in growth.

Conclusions

This research utilises a ring width index analysis for bioindication of tree/stand vitality. Ring width indexes are calculated in order to minimise the influence of age on the increment trend, that is, to better view the reaction of trees to exogenous factors. With regard to biondication of vitality, with reference to ring width index specifically, we can conclude that trial plot 13 features the best results, while trial plots 5 and 10 feature potentially the worst ones.

Summarising the explored stands, it can be concluded that their vitality is solid and that possible devitalisation in the future can be prevented by the application of appropriate silviculture measures.

MONITORING ON APPEARANCE AND SPREAD OF HARMFUL INVASIVE PATHOGENS AND PESTS IN BELASITSA MOUNTAIN

Margarita GEORGIEVA*, Georgi GEORGIEV, Plamen MIRCHEV, Eva FILIPOVA

Forest Research Institute, Bulgarian Academy of Sciences, Bulgaria
*Corresponding author: margaritageorgiev@gmail.com

Abstract

Belasitsa Mountain is located on the territory of Southwest Bulgaria, Northern Greece and Northern Macedonia. The Bulgarian part of the mountain includes most of its northern slopes and ridge territories, characterized by variety of vegetation zones and plant communities. At lower altitudes, *Quercus* spp., are the most distributed, but gradually replaced by the sweet chestnut forests (*Castanea sativa*). Chestnuts are distributed between 400-1300 m a.s.l., forming the largest natural locality in the country. Along the river valleys in the mountain, natural population of *Platanus orientalis* occurs. Since 2018, a system for monitoring of two pathogens (*Cryphonectria parasitica* on *Castanea sativa* and *Ceratocystis fimbriata* on *Platanus orientalis*) and three invasive pests (*Corythucha arcuata* on different oak species and chestnut, *C. ciliata* on *P. orientalis* and *Dryocosmus kuriphilus* on chestnut forests) has been implemented. Until now, a high density of *C. ciliata* was established on *P. orientalis* causing significant damages on host trees. *C. arcuata* has spread in Bulgaria since 2013. Over the next few years, the species penetrated many regions of the country by affecting predominantly oak forests, but in 2017, it was registered for first time on the chestnut trees. In Bulgaria, *D. kuriphilus* has not been found yet, but as the pest was established in Greece in 2014, natural spreading of the species to Belasitsa Mt. could be expected. The possible penetration of this pest could increase the rate of damaged stands that had already been severely attacked by the fungal pathogen *C. parasitica.*

Key words: *invasive pests, monitoring, Belasitsa Mt., Bulgaria*

Introduction

Belasitsa Mountain is located on the territory of three countries: Bulgaria, Northern Greece and Northern Macedonia. The mountain is about 60 km long and 7 to 9 km wide. Its main massif is oriented in east-western direction. The climate is characterized by strong Mediterranean influence: precipitation is at its highest in the autumn and winter, and at its lowest in the summer. Bulgarian part of the mountain includes most of its northern slopes and ridge territories. It is characterized by variety of vegetation zones and plant communities. *Castanea sativa* Mill. population located on the northern slopes of Bulgarian part of Belasitsa Mt., at attitudes from 500-600 up to 900-1000 m a.s.l. This population is the largest and most valuable one at the Balkan Peninsula. It is also among the few well preserved autochthonous populations of this species in Europe. Most investigations on natural *C. sativa* forests in Europe and at the Balkan Peninsula in particular, reveal progressive degradation of this species, even in nature protected territories. The area occupied by the *C. sativa* forests on the northern slopes of Bulgarian part of Belasitsa Mountain is around 1400 ha. Natural stands cover an area of about 650 ha. More than 90% of them are older than 100 years of age, and around 75% are older than 140. Most natural stands are in poor health condition: with dieback in the crowns.

Pests and fungal pathogens are a part of the natural biocenoses complex inhabiting different types of ecosystems. Their development in plants causes destructive processes that have negative influence on the vitality and productivity of the trees. During the last years,

introduced pests and pathogens have turned into growing threat for the natural plant species disturbing the biodiversity and ecological dynamics in forest ecosystems.
The aim of study was to determine penetration of invasive pathogens and insect pests threatening tree vegetation in Belasitsa Mountain.

Materials and methods

In 2018, a network of 14 sample plots (SPs) was established in Bulgarian part of Belasitsa Mt. in outskirts of six settlements (Table 1). Three SPs were selected in *Platanus orientalis* L. stands for monitoring of *Corythucha ciliata* (Say, 1832) (Hemiptera: Tingidae) and *Ceratocystis fimbriata* Ellis & Halsted *f.sp. platani* (J.M. Walter) Engelb. & T.C. Harr (Microascales: Ceratocystidaceae) and the remaining ones – predominately in *Castanea sativa* and *Quercus petraea* Liebl. stands for monitoring of *Cryphonectria parasitica* (Murrill) Barr. (Diaporthales: Valsaceae), *Corythucha arcuata* (Say, 1832) (Hemiptera: Tingidae) and *Dryocosmus kuriphilus* Yasumatsu, 1951 (Hymenoptera: Cynipidae).

Defoliations caused by biotic and abiotic stresses were assessed according to the European methodology of the UNECE International ICP Forests Program (Eichhorn et al., 2010).
The studies were carried out by periodical observations and collection of biological material (leaf, twigs, bark and branches) for laboratory testing at the Forest Research Institute, Sofia. Isolation of the fungi into pure cultures on PDA (Difco) nutrient media was done. The colonized fungi were further identified by combination of colony macroscopic (colour, morphology and growth rate) and microscopic characteristics (spore shape, size, colour and morphology).
During the growing seasons, samples of leaves and shoots were collected regarding the presence/absence of studied species and the intensity of the attack (expressed as percentage of injured leaves). The attack intensity was assessed by the degree of foliage fading, as a deviation from the normal colour of the host tree leaves. Larvae of insect pests were placed in entomological boxes and photo eclectors to obtain adult emergence. Adult insects, nymphs and eggs were also collected for species identification.

Results and discussion

In this study, only *Cryphonectria parasitica* was established on *Castanea sativa*, and *Corythucha ciliata* – on *Platanus orientalis* L. The remaining invasive insect pests, *Corythucha arcuata* and *Dryocosmus kuriphilus*, as well as the pathogen *Ceratocystis fimbriata f.sp. platani* were not detected in Belasitsa Mt. Distinct decline in crown condition was observed in sampled chestnut trees.

The assessing of the distribution of *C. parasitica* carried out in this study shows that from the sites of primary infection, the disease has been spread across the whole mountain, between 400 and 800 m a.s.l., affecting 85% of the surveyed trees. Only 15% of chestnut trees were classified as healthy (defoliation of up to 25%). In the areas, located at higher altitude (between 700 and 900 m a.s.l.), the rate of infected by *C. parasitica* trees were only 10%. The effect of trees decline varied from partial crown dieback to completely death trees (18%). In individual SPs, chestnut blight incidence ranged from 18% to 100% of the trees in the SPs, and mortality caused by the fungus was between 2% and 80%. The results obtained indicated that chestnut blight had spread into most chestnut stands of Belasitsa Mt., the most affected stands between 400-800 m. a.s.l.

The pathogen *Cryphonectria parasitica* was found to be widely distributed in all studied SPs in in Belasitsa Mt. It causes chestnut blight disease and is considered to be the most destructive pathogen on both American (*Castanea dentata* (Marsh.) Borkh.) and European chestnut (*C. sativa*) (Anagnostakis, 1987). The first documented observation of *C. parasitica* in Bulgaria was on chestnut trees in pure and mixed stands on the northern slopes of Belasitsa Mt. and on the Eastern Rhodopes mountain in 1993 (Petkov, Rossnev, 2000). The pathogen is detected in both largest localities of chestnut in Bulgaria – in Belasitsa Mt. and West Balkan Range, and causes serious damages on stems and branches (Georgieva et al., 2013). *C. parasitica* attacks bark tissues producing cankers that can develop as sunken regions due to tissue collapse, damage to vascular tissues produces wilts and diebacks. A high infection rate and crown defoliation of the chestnut trees manifest that chestnut blight disease was a major stress factor and likely an important driver of chestnut decline. Epidemic of disease reduces the abundance of a dominant native species, resulting in a change in landscape structure. The infected dead branches with wilted, yellow or brown leaves which remain hanging on the branches, producing a so-called flag. The stems developing numerous epicormic shoots below the necrotic areas. A parasitic fungus causing necrotic lesions (cankers) on the bark of chestnut stems and branches. The pathogen attacks all the aerial parts of the tree: the main stem, branches and young suckers; infecting the tree via wounds in the bark and forming sunken canker due to necrosis and collapse of bark tissue (Hebard et al., 1984). The buff-brown mycelia of the fungus invade and destroys the inner bark (i.e. phloem, vascular cambium and xylem) resulting in the death of host tissue distal to the point of infection. Thus, the disease leads to the loss of an important part of the chestnut production and the progressive death of the tree.

The sycamore lace bug, *Corythucha ciliata* was found at high density in the three studied SPs (Petrich, Kolarovo and Samuilovo) in Belasitsa Mt. Additional surveys showed that the species was penetrated in *Platanus orientalis* stands along the rivers and streams in the mountain. It is naturally distributed in USA and south parts of Canada. In Europe the species was found for first time in Italy in 1964 and later in other countries (France, Switzerland, Croatia, Greece, etc.). In Bulgaria the pest was found for first time in 1989 in Sofia (Josifov, 1990). Currently, it is distributed all over the country. The species is trophycally related to plane trees (sycamore) (*Platanus* spp.). In urban environment in Bulgaria it frequently feeds on *Platanus x acerifolia* (a hybrid between *Platanus occidentalis* and *P. orientalis*). It has penetrated into all natural localities of *P. orientalis* in the country. In Europe, *C. ciliata* usually develops two generations per year, but in some south regions with Mediterranean

climate it has three. The female lay eggs around the nerves on the lower leaf's surface. The larvae and adults feed in groups on the lower surface and the colonies could reach scores and hundreds of specimens. The generation develops within 45 days. The second generation appears at the end of August/beginning of September. It winters as imago in bark crevices of thick branches and stems. At the places where larvae and imago were feeding, small white spots appear. Later the spots grow, and this leads to leaf depigmentation and yellowing. In case of massive attack, the leaves dry and fall prematurely at the end of summer. In combination with other stress factors the massive development of *C. ciliata* during some consecutive years could lead to ruin of the attacked trees. It should be noted that the damages caused by the pest are most significant in urban conditions (Georgiev et al., 2017).
The oak lace bug, *Corythucha arcuata*, is naturally distributed in North America. In Europe the species was found for first time in Italy in 2000 (Bernardinelli, Zandigiacomo, 2000). In 2002 was reported for Switzerland (Forster et al., 2005), and in 2003 for Turkey (Mutun, 2003). In Bulgaria it was found a new species for the Balkan Peninsula in 2012 in the region of Plovdiv and Simeonovgrad (Dobreva et al., 2013). Later, invasion of the oak lace bug (*C. arcuata*) was reported in it in Hungary (Csóka et al., 2013), Croatia (Hrašovec et al., 2013), Romania (Tomescu et al., 2018) and other countries. In its natural area, *C. arcuata* feeds mainly on *Quercus* spp., and rarely representatives of other genera (*Castanea*, *Acer*, *Pyrus*, *Malus*, *Rosa*). In Europe, it was found on *Quercus petraea*, *Q. robur, Q. pubescens, Q. cerris, Q. rubra*, *Rubus idaeus*, *R. ulmifolius, Castanea sativa* and *Rosa canina* (Dobreva et al., 2013). *C. arcuata* biology and ecology is similar to that of Sycamore lace bug (*C. ciliata*). The feeding of larvae and adult colonies causes depigmentation, aging and premature leaf falling. Recently, the species was found on 8 oak species in high number nearly all over Bulgaria, on *Castanea sativ*a in Plovdiv region and on 5 occasional tree and shrub hosts (Simov et al., 2018). In case of penetration in Belasitsa Mt., *C. arcuata* could turn into a danger for chestnut stands due to progressive degradation and the poor health condition of the species.
The quarantine pest *Dryocosmus kuriphilus* causes severe damage to species of *Castanea* genus. It is widely spread in China, Korea and Japan, and in 2002, it first appeared in Italy. After the first penetration of the pest in Europe, it has spread rapidly in several other European countries, probably due to the trade in chestnut plant material. Despite the measures taken to prevent further spread of this pest in other countries, it was first obtained in Greece in 2014 (Michaelakis et al., 2016). However, studies show that the pest is still very limited in Greece. In Bulgaria, the species is not found at present, but its possible penetration at Belasitsa Mt. will increase the damage caused by *Cryphonectria parasitica*, which has caused significant losses in chestnut forests over the last 20 years.
The pathogen *Ceratocystis fimbriata* is an introduced fungal pathogen from North America to South Europe, distributed on species from genus *Platanus*, causing destructive tracheomicotic disease. Since 2004, the disease has been detected in southwest parts of Greece, where it caused dead of natural plantations and urban trees (Tsopelas, Angelopoulos, 2004). *Platanus* species are the only hosts for pathogen, with highest sensibility being *P. acerifolia*, often used for planting in urban environments in the countries with moderate climate. In transversal cut of the stem blue-black coloration growing radially to the periphery, with fusiform patterns could be observed. The dead cambial tissue provokes appearance of dark longitudinal spots on the bark surface. These spots are very important characteristics for diagnostics even if the infection has penetrated through the roots. Infection with the pathogen *Ceratocystis platani* f.sp. *platani* develops in the places of injuries on the bark or root, stem or branches, timber during pruning or other mechanical damages. After fungus spores appear on the plant tissue fast distribution starts in the xylem tissue along the stem and radially to its core. The fungus

could overwinter at temperatures up to -17°C, but does not develop under 10°C and over 45°C.

Conclusion

Finally, it should be noted that monitoring of invasive fungal pathogens and insect pests threatening forest vegetation in Belasitsa Mt. should continue to take adequate measures in case of penetration of highly aggressive species. This is mainly true for species whose health status is severely degraded, such as chestnut (*Castanea sativa*), as well as another species of high conservation significance, the eastern plane (*Platanus orientalis*).

Acknowledgments

The results was obtained during the project implementation 'Health status of European chestnut (*Castanea sativa* Mill.) in Belasitsa and Ograzhden and measurements for improvement', funded by the South-West State Enterprise-Blagoevgrad, Executive Forest Agency.

Abstract

Since 1986, Bulgaria has been a part of the International Cooperative Program 'Forests' launched in 1985 under the auspices of the United Nations for European Economic Commission (UN/ECE). During the period 1986-1989, a large-scale network of 256 observation plots were set in ten regions throughout the country in order to monitor the health condition and dynamics of changes occurring in forest ecosystems. During the period 1986-2009, experts from Forest Research Institute, Bulgarian Academy of Sciences, annually conducted assessments in 130 permanent observation plots in five regions of the monitoring network. Among all plots, 54 were established in Austrian pine (*Pinus nigra* Arn.) and Scots pine (*P. sylvestris* L.) stands. In 2009, the number of plots was reduced to 80, as twenty-seven of them (predominantly plantations) were set in pine stands with 696 *P. sylvestris* and 384 *P. nigra* trees. The health status of trees in natural pine stands remained unchanged for the entire studied period. In recent years, worsening of *P. sylvestris* plantations has been observed at lower altitudes (below 700 m a.s.l.). Insect pests mainly bark beetles, and fungal pathogens, were the most frequent causers of damages. Snow- and wind-throws damages often occurred provoking the bark beetle attacks.

Key words: *pine stands, monitoring, health status, Bulgaria.*

Introduction

The forests of Bulgaria cover 4.1 million ha that is 37.7% of the territory. Broadleaved forests account for 68% of the forest area, and conifers account for 32% of the area. In 1960s, large-scale afforestation was carried out to converse the abandoned land with tree plantations to control the deterioration and soil erosion. The most commonly planted coniferous species comprised native Austrian pine (*Pinus nigra* Arn.) and Scots pine (*P. sylvestris* L.). The share of forest plantations amounts to 20.9% from the total forest area in the country. The International Cooperative Program 'Forests' launched in 1985 in Freiburg under the auspices of the United Nations for European Economic Commission (UNECE) with the adopted methodology for forest assessment and monitoring. Since 1986, Bulgaria is actively involved in the implementation of the ICP Forests. During the period 1986-1989, a network of 256 permanent observation plots (POPs) were set up in ten regions throughout the country to monitor the health status and dynamics of changes occurring in forest ecosystems. Observation plots were set in a systematic transnational grid of 16 × 16 km in 10 regions throughout the country to gain insight into the geographic and temporal variations in forest condition. Scientific experts of the Forest Research Institute - BAS have conducted observations in five of them (2nd - northern slopes of Middle Stara Planina Mt., 3rd - Eastern Stara Planina Mt., 4A- southern slopes of Middle Stara Planina and Sredna Gora Mts., 5th - Osogovo, Kraishte, western slopes of Rila and Vitosha Mts. and 6th - the mountains of Southwestern Bulgaria). During the period 1986-2009, annual observation was conducted in 130 permanent observation plots. Among them, 54 were established in *P. nigra* and *P. sylvestris* stands. In 2009, the number of observation plots was reduced to 80.

The annual reports present the scientific findings for Bulgaria, covering major challenges regarding the future preservation and management of forest ecosystems under environmental change. The results have shown that environmental factors and damages caused by abiotic and biotic agents fluctuated in years and need to be considered for assessment of tree health condition (Mirchev et al., 2006; Velizarova, 2010, Velizarova et al., 2013). The fluctuations add another degree of uncertainty to the survival of observed tree species. Special attention has been paid to the worsening of the health status of pine plantations in Southwestern Bulgaria for the period of 1986-2005 (Rossnev et al., 2008) and for 2000-2012 (Mirchev et al., 2014). This current study presents data on the health status of pine plantations in the five observed regions, covering the period 2009-2018.

Material and methods

Duringthe period 2009-2018, twenty-seven plots (predominantly plantations) were monitored in pine stands with 696 *P. sylvestris* and 384 *P. nigra* trees. All *P. sylvestris* plots were located in Southern Bulgaria andfive of them werelocatedin natural stands at 1302-1520 m a.s.l. These stands aged from 70 to120 years (table 1). Thirteen pots were set in tree plantations that aged from 50 to78 years and these stands were located at an altitude from 320 to 1298 m. All ten observation plots are set in *P. nigra* plantations in both Northern and Southern Bulgaria at 80 m a.s.l. (Varna) to 951 m a.s.l. (Klisura, Sofia distr.) (table 2). Most observation plots were at flat terrains and predominantly exposed in south direction.

An observation plot in Petrich (6^{th} region) represented mixed forest of 23 *P. nigra* and 17 *P. sylvestris* trees. The assessment of the general health status of 1084 trees was carried out according to the Manual of assessment of crown conditions of ICP 'Forests' (Eichhorn, 2010). Two physiological indicators were included in the complex assessment of the trees: defoliation and discoloration, characterizing the health of the trees, affected by several anthropogenic and natural factors. The surveys were conducted in combination with detailed assessments of biotic and abiotic damage causes. Defoliation was estimated in 5% steps, ranging from 0% (no defoliation) to 100% (dead tree), grouped into five classes: '0' (0-10% - no defoliation), '1' (>10-25% - slight), '2' (>25-60% - middle, '3' (>60-<100% - severe) and '4' (100% dead trees).

The general health status was quantified as a weighted arithmetic mean of the complex assessment on health status obtained by the formula:

$$Weighted\ Arithmetic\ Mean = \frac{\sum 0n_0 + 1n_1 + 2n_2 + 3n_3 + 4n_4}{\sum n_0 + n_1 + n_2 + n_3 + n_4}$$

where:

0, 1, 2, 3, 4 - complex assessment;

n_0, n_1, n_2, n_3, n_4 - number of tree in the respective degree.

Results and discussion

For the period 2009-2018, a serious deterioration of Scots pine (*P. sylvestris*) health status was noticed. Mean defoliation increased from 1.4 (slight damaged) in 2010 to 2.0 (middle damaged) in 2018 in both natural stands and plantations (fig. 1). In all natural stands, withering was found at the end of observation period with a more significant degree at Leeve, Rila Mt. (table 1) after snow damages in 2015 that changed stand structure. Disturbances, caused by biotic agents, were the most frequent in Scots pine plantations. In 69.2% of them, symptoms of drying were observed for the entire studied period. In 2016, in Zavala (Kraishte Mt.), the share of completely dead trees reached up to 90% due to root rot fungus

(*Heterobasidion annosum* (Fr.) Bref) and bark beetle (*Ips acuminatus* Gyllenhal, 1827). The assessment of health status in observation plots in Vitosha Mt. (Selimitsa and Dren) and in Osogovo Mt. (Lisets) (table 1) obtained similar results. A long-term increase of mean defoliation and a significant decrease in the tree vitality was observed related to isolated water shortages and outbreaks of bark beetles. The value of mean defoliation rose by 76.9% at the end of the observation period, which was indication for deteriorated health status of all Scots pine plantations. General deterioration was observed in Austrian pine (*P. nigra*) that was more evident in the period 2016-2018 (fig. 1). The value of mean defoliation increased from 1.05 (slight damaged) to 2.1 (middle damaged). The percentage of healthy trees decreased but so far in lower rate than *P. sylvestris*. The number of dead or missing trees has slightly decreased and reached 40% for the studied period. The mortality of trees is mainly due to decline processes related to pathogens *Diplodia sapinea* and *Dothistroma* spp., caused damage to all trees in the plots. The data for the whole study period show that in the studied regions of Bulgaria the health status of *P. sylvestris* and *P. nigra* were similar or very close in values. The fluctuations observed during the years are synchronous for both species. After 2015, there was a steady trend of deterioration in the health status of both tree species (fig. 1).
With regards to the determined biotic factors, the population of pine bark beetle (*Ips acuminatus*) dramatically increased and caused serious damage to the Scots pine stands in the monitored sample plots. Limited damages were observed by *Tomicus piniperda* (L). and *Thaumetopoea pityocampa* (Den. Et. Schiff.) which caused physiologically weakening of trees in pine plantations. The presence of the fungus *H. annosum* was observed in both the *P. sylvestris* and *P. nigra* stands. The pathogens *Dothistroma pini* Hulbary, *D. sapinea* and *Cyclaneusma minus* (Butin) DiCosmo, Peredo and Minter were also found in these plantations. These pathogens cause damage to needles and shoots, and therefore pose a threat to the monitored tree stands. Numerous factors determine the health condition of forests. These include climatic factors, disease and insect damage as well as other biotic and abiotic factors. Long-term monitoring provides baseline data on the distribution, occurrence and harmfulness of biotic agents or damage factors in Europe. These data are contributing to other aspects relevant for forest policy like sustainable forest management (Eichhorn et al., 2016).
An increased incidence of trees with severe defoliation (class '3' and '4') was found out both in *P. sylvestris* and *P. nigra* plots almost throughout the whole territory of the country, affected by a bark beetle calamity, mainly at lower altitude. The ecological problems were particularly manifested in plantations. Some of pine plantations were planted for the restoration of degraded lands, in atypical habitats at lower altitudes where early pine mortality was registered (Popov et al., 2015, 2016). A process of incremented damages by biotic and abiotic factors contributes significantly to the rapid destruction of pine plantations in the country. Among the abiotic factors responsible for the deterioration of pine plantation, damages caused by wind, wet snow and ice have the most negative impact. Damages from natural anomalies are regularly observed in Bulgarian forests on larger or more limited areas. However, their frequency and strength are increasing, creating prerequisites for appearance of xylophagous pest calamities and disease development. Among xylophages, the most dangerous and economically harmful for pine trees is *Ips acuminatus*, and among diseases - root rot caused by the fungus *Heterobasidion annosum* (Mirchev et al., 2016).

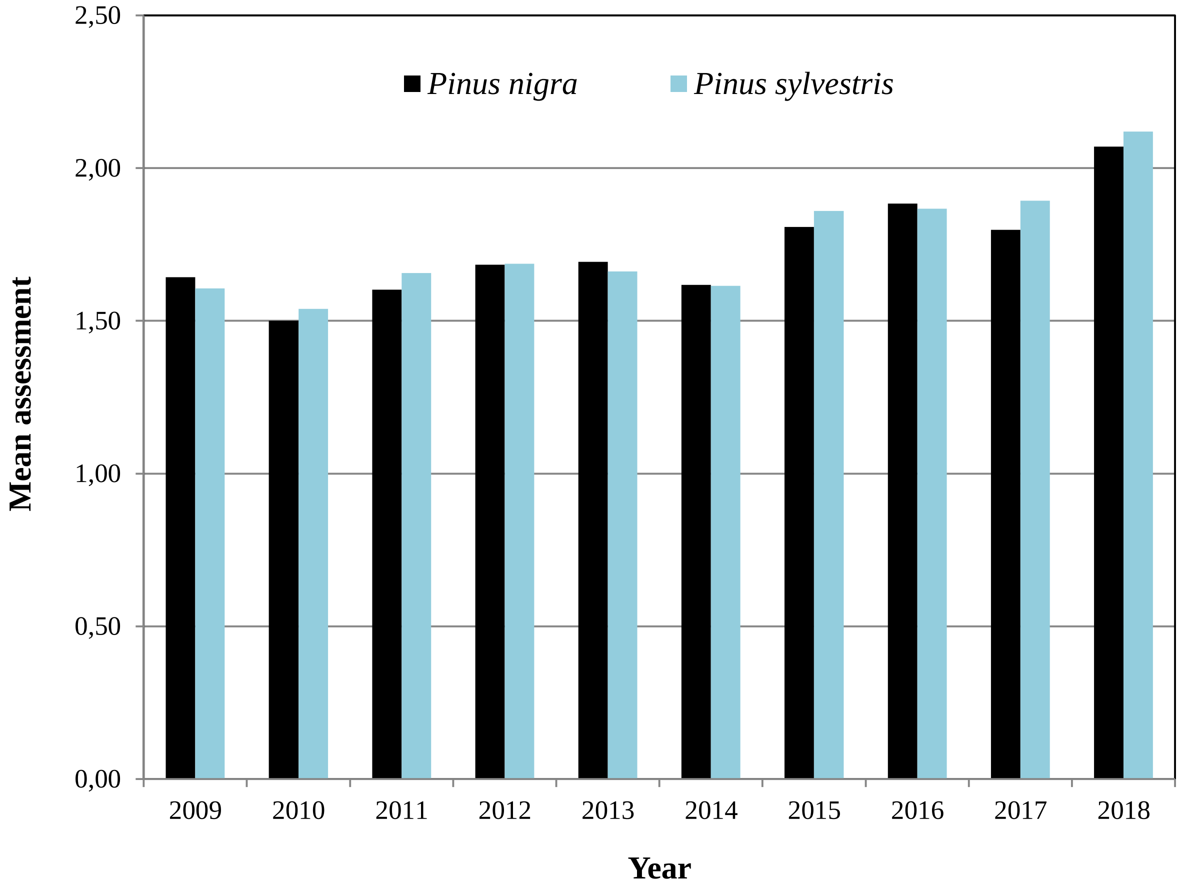

Figure 1. A weighted arithmetic mean of complex assessment on health status of studied *P. sylvestris* and *P. nigra* during the period 2009-2019

Conclusions

In conclusion, it should be noted that the health status of pine trees in natural stands remained unchanged for ten-year period. In the plantations, worsening of trees has been observed at lower altitudes (below 700 m a.s.l.). Insect pests mainly bark beetles, and fungal pathogens, were the most frequent causers of damages. Snow- and wind-throws damages often occurred provoking the bark beetle attacks. Among the abiotic factors responsible for the deterioration of pine plantation, damages caused by wind, wet snow and ice have the most negative impact.

The long-term monitoring provides baseline data on the distribution, occurrence and harmfulness of biotic agents or damage factors. The assessment of harmful impact and spread of the most important insect pests and fungal pathogens causing damages in Bulgarian forests is essential for making decisions about management of pine plantations. The identification of the pests and pathogens and the determination of their specific ecological features will allow the development of integrated measures for limiting their negative impact.

Acknowledgements

We would like to acknowledge and thank to the Executive Environment Agency (NFC of ICP Forests) for the data provided by the National Programme for Monitoring of forest ecosystems. The Ministry of Environment and Water financially supported the programme with the Enterprise Management of Environment Protection Actions. The authors are most grateful to Dr. Dimitar Nedyalkov for his help in preparing the data and figures.

INVESTIGATING FACTORS AFFECTING CONSUMPTION OF CONSTRUCTION TIMBER FOR TEN SELECTED EUROPEAN COUNTRIES. A FOOTPRINT APPROACH

Panagiotis KOYLELIS*

Abstract

Europe is a world leading producer and consumer of wood products, which generates a substantial forest "footprint" both inside and outside European borders. However, there has been limited research on what factors shape consumption, and in particular, the relative roles of local forest abundance, forest production and economic wealth. This paper helps to address this issue, by assessing the relationship between few key variables–consumption of construction timber, forest area, GDP and finally forest products footprint. Ten European countries were selected, ranging from countries with very high forest cover and low population density to those with very low forest area per capita. Pearson correlation was employed. It was found that, on average, the wood products consumption is more related to people in more forest-endowed countries than those in countries with less forest per capita. However, this relationship shows regional variation. In other words, higher rates of forest areas appeared to support higher rates of consumption rather than lower imports or "external footprints". The results for per capita GDP revealed a significant correlation with per capita consumption, primarily within the examined emerging economies. This decoupling of wood consumption from GDP in wealthier countries is consistent with past studies. Finally, significant correlation was found between footprint and sawnwood consumption almost across all the case studies, while in only three of them wood panels consumption was related to footprint. All of these observed patterns, taken together, highlight the need for additional research to understand the causal factors and net environmental and social impacts.

Keywords: *Consumption, forest products, forest footprint, GDP, correlation.*

Introduction

The focus of this article is on the EU forest sector. Europe is a world leading producer and consumer of wood products and this leaves a substantial 'footprint' both inside and outside its boundaries. The ecological footprint measures human appropriation of ecosystem products and services in terms of the amount of bioproductive land and sea area needed to supply these services (Wackernagel and Rees, 1996). The ecological footprint and biocapacity accounts for six land use types: cropland, grazing land, fishing ground, forest land, built-up land, and carbon uptake land (to accommodate the carbon footprint) (Ewing et al., 2010). To date international concern has focused primarily on the EU's external forest footprint, and the extent to which it can be linked to illegal logging (e.g. Lawson and MacFaul, 2010) or consumption of products, such as palm oil and soy, that are driving deforestation elsewhere (e.g. Cuypers et al., 2013). However, there has been relatively little attention to the factor's driving the total size of Europe's wood product consumption.

Considering only the volume of wood consumed, European consumption has remained well within its capacity to produce that wood (e.g. Global Footprint Network 2012; UNECE, 2013). Nevertheless, there is considerable variation in the environmental and social impacts of wood production across the many countries from which Europe sources its wood. Furthermore, regardless of where the wood is produced, there are inherent tradeoffs between

production and other social and ecological values associated with forests. For all of these reasons, it is important to better understand the key factors driving total wood consumption. There has been very little empirical research to date examining the variables driving per capita consumption of wood products, with the exception of (Haripriya and Parikh, 1998) and (Humerkoski et al., 2015). In addition is reported by O’Brien et al., (2018) that the existing subsidy schemes for bioenergy in the EU are expected to increase dependency on wood imports (Schulze et al., 2012; UNECE et al., 2012), creating -extra- future global land demand, on behalf of EU. Nevertheless, most predictions of future wood consumption assume a close relationship between per capita consumption rates and per capita GDP, with a leveling off past a certain threshold of economic development (e.g. Jonsson, 2012). Yet countries that have passed that threshold still vary considerably in the quantity of wood the average resident consumes. This raises questions about what other variables might explain this variation. Past research has highlighted important regional differences in wood consumption (Buongiorno, 2009), and the relative importance and persistence of local building traditions in determining the choice of construction material (Mahapatra and Gustavsson, 2008). In partial explanation of such differences, Humerkoski et al.’s (2015) study of European sawnwood consumption suggests a correlation between a country’s forest growing stock per capita and consumption per capita. This would suggest, not surprisingly, that there is a historical tradition of using wood for construction in countries where there is a relative abundance of wood, and that these traditions have persisted despite the globalization of wood trade. However, Humerkoski et al., also find that the precise relationship between forest abundance and per capita consumption varies by region (ibid), and hence other variables must also be significant.
There is growing international interest in the concept of ecological footprints, or related measures that assess and compare consumption levels and their impacts on the earth’s productive capacity (e.g. Steen-Olsen et al., 2012; Wiedmann et al., 2013; and Steffen et al., 2015). However, there is limited research attempting to explain differences in consumption levels, particularly among countries with similar levels of economic development.
This article tries to approach this issue, by assessing the relationship between three key variables which could be related to footprints – i.e. per capita consumption, forest area and GDP. Finally, it investigates which subcategory of construction timber sawnwood seems to play more important role in footprint creation for each case study.

Material and methods

The analysis was focused on consumption of construction timber as primary timber (sawnwood and wood based panels) in ten case study countries based on the reasoning that levels of forest endowment are more likely to affect choices in building materials for which many substitutes are available, than use of products like paper for which there are fewer substitutes. Paper production is also subject to intense global price competition, favoring large-scale, high technology production and locations with high fiber productivity.
Figures for the consumption of construction timber per capita and the GDP per capita were collected from FAOSTAT and the EUROSTAT database (EUROSTAT, 2014) for the period 1995-2013. For construction timber we combined the FAO data on sawnwood and wood-based panels. The former consisted of the sawnwood+ (total) category, which includes coniferous and non-coniferous production in cubic metres. The latter consisted of the wood panels + (total) category, which includes veneer sheets, plywood, particle board and fibreboard as defined by FAO (FAO, 2012). Population data were drawn from (FAOSTAT, 2014) in order to convert the consumption figures into units per capita.
The analysis was centered around the functions of

$$\frac{Consumption}{capita} = f\left(\frac{production}{capita}, \frac{GDP}{capita}\right) \qquad (1)$$

for construction timber, with consumption/capita being the dependent variable and production/capita and GDP/capita being the 'independent' variables. The use of GDP of is very common to the forest sector models which are defined by Solberg (1986). EFSOS (European Forest Sector Outlook Study) model (Kangas and Baudin, 2003) and EFSOS II (UNECE/ FAO, 2011) use GDP as the best reflecting variable for economic growth in order to make projections about forest products demand, supply and trade in Europe. The second updated part of the analysis is aiming to determine if there is a statistically significant relationship between the forest products footprint and the consumption of construction timber (function 2).

$$\frac{\text{Forest products footprint}}{\text{capita}} = f\left(\frac{\text{sawnwood consumption}}{\text{capita}}, \frac{\text{woodpanels consumption}}{\text{capita}}\right) \qquad (2)$$

The data regarding forest products footprint for each country were received from the Global Footprint Network open database (Global Footprint Network, 2018) for the period 1990-2016. Correlation analysis was employed using the Pearson correlation coefficient. The statistical analysis was performed with SPSS (version 22.0) statistical package (Norusis, 1997).

Results and discussion

Ten European case study countries (involved in INTEGRAL project) were chosen for the analysis, representing a wide range of per capita production rates and/or forest areas (related to potential production rates) (Table 1). Sweden, Lithuania and Portugal represent countries with high levels of per capita industrial roundwood production followed by France, Germany, Ireland and Slovakia with medium levels of per capita production. The case study countries with low levels of industrial roundwood productivity are the Netherlands, Bulgaria and Italy. Bulgaria is unusual among the case studies, in that its forest area/capita is relatively high but its levels of industrial forest production are relatively low.

Table 1: Case study countries industrial production and forest area per capita

	N Europe	CE Europe	S Europe
High production/capita	Sweden	Lithuania	Portugal
Industrial production (cum)/capita (Average 2000-2013)	7.05	1.45	0.91
Forest area/capita (2012)	2.97	0.72	0.33
Medium production/capita	Germany	Slovakia	France
Industrial production (cum)/capita (Average 2000-2013)	0.56	1.37	0.47
Forest area/capita (2012)	0.21	0.36	0.25
	Ireland		
	0.59		
	0.17		
Low production/capita	Netherlands	Bulgaria	Italy
Industrial production (cum)/capita (Average 2000-2013)	0.05	0.39	0.05
Forest area/capita (2012)	0.02	0.55	0.15

Source: FAOSTAT 2014

The general trend of correlation between consumption of forest products and economic growth (and population sometimes), measured by GDP, is intuitive given the wide variety of usage ranging from construction material to furniture or paper. One known major exception of this trend is fuelwood for which a decline in consumption is observed as GDP per capita rises as people shift to more convenient fuel sources once these become affordable for them (Buongiorno et al., 2003; Whiteman et al., 1999). In doing so, was realized the converse role of production in the function as long as increased consumption can increase demand for timber and drive increases in domestic production. At the same time, we the possibility of the converse relationship – that is whether higher levels of domestic production (due to changes in price, ease of availability or other factors) might spur consumption, seems really interesting. The existing observations about higher wood consumption in leading wood producing countries, coupled with evidence that in most cases GDP alone does not explain consumption, suggests the possibility of this latter effect. If domestic production spurs domestic consumption, in addition to consumption spurring domestic production, this needs to be taking into account in assessing strategies to reduce ecological footprints.
Given the dearth of existing studies on exactly which variables distinguish one regional wood culture from another, it is likewise not possible to classify which countries belong to which regional grouping. However, in the EU at least, even simple divisions between north, east, west and south yield much stronger regional correlations between wood abundance and consumption than for the EU as a whole. For example, a strong positive correlation was found, between per capita forest area and per capita consumption of construction wood (sawnwood, wood based panels) among the eastern emerging economies of the EU, consisting of Hungary, Poland, the Czech Republic, Romania, Slovakia, Croatia, Bulgaria, Slovenia, Lithuania, Latvia and Estonia (p=0.001) (Table 2). Likewise, there is a significant correlation in the Scandinavian countries of Denmark, Sweden and Finland (p= 0.01) and an equally significant correlation among other Northwestern countries. In contrast, there is no apparent correlation in the more Southern EU countries of Italy, Cyprus, France, Portugal, Greece and Spain. This latter result may be explained, for example, by the risk of fire or other climatic variables shaping wood use.[18]

Table 2. The correlation between forest area and consumption for selected groups of EU countries.

		Pearson correlation coefficient	**Significance level**
EU countries		Forest area/cap	
E	total cons/cap	0.864	P<0.05
N	total cons/cap	1	P<0.05
NW	total cons/cap	0.773	P<0.05
S	total cons/cap	-0.348	**P=0.449**

East group includes: Bulgaria, Croatia, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Romania and Slovenia
North group includes: Denmark, Finland and Sweden, Northwestern group includes: Austria, Belgium, Germany, Ireland, Luxemburg, Netherlands and UK
South group includes: Cyprus, France, Greece, Italy, Portugal and Spain

[18]The source of the data for these calculations was (FAOSTAT, 2014) and the p values are based on data from the year 2012.

Whatever the precise combination of variables that determine regional differences, the above evidence is sufficient to suggest a significant relationship between wood abundance and wood consumption that merits further exploration. Furthermore, it is also important to interrogate how much of this relationship is based on durable traditions of wood use and/or whether fluctuations in wood availability within a given country are accompanied by changes in consumption. The following analysis addresses the latter by comparing the production of construction wood (sawnwood, wood based panels) per capita with forest apparent consumption[19] per capita over a period of 18 years within ten case study EU countries. In addition, we include GDP per capita as another important variable, independent of wood culture. The results of this analysis which described in methodology for the case study countries are presented below [tables 3,4].
Correlation analysis based on Pearson’s r indicated that regarding sawnwood there is a positive relationship between consumption/capita and production/capita for all the countries. The Pearson correlation coefficient for this variable ranged from 0.53 for Germany to 0.94 for Slovakia (Table 3). On the other hand, the Pearson correlation coefficient ranged from 0.44 for Sweden to 0.84 for Lithuania regarding the GDP/capita. Positive relationships between GDP per capita and sawnwood/capita were found for all three Eastern emerging economies, i.e. Lithuania, Slovakia and Bulgaria, but were not found consistently for developed economies. This is consistent with other research, which indicates that wood consumption tends to increase with GDP and then levels off among fully industrialized countries (e.g. Jonsson, 2012). For France, Germany and Ireland there wasn’t any correlation between sawnwood consumption/capita and GDP/capita. Thus, production/capita is the variable that correlates most strongly with consumption/capita and GDP/capita has either a positive or a negative (Netherlands and Portugal) correlation, probably determined in part by level of economic development.
As regards to wood panels there is a positive relationship (variables tend to increase together) between consumption/capita and production/capita for the eight of 10 case studies and in one (Sweden) there is a negative correlation. In the Netherlands there is no significant correlation. The Pearson correlation coefficient for this variable ranged from 0.59 for Ireland and Portugal to 0.91 for Slovakia (Table 3). The Pearson correlation coefficient ranged from 0.56 for Portugal to 0.99 for Lithuania regarding the GDP/capita. For the Netherlands, Germany and Ireland there wasn’t any significant correlation between consumption/capita and GDP/capita. Thus, wood panels production/capita and GDP/capita correlate quite strongly with consumption/capita for most of the countries. It’s important to underline here that in most of the cases above, the findings are designated as significant ($p<0.05$).

n.s: not significant

Finally, the last part of our analysis indicated that there is significant correlation between forest products footprint and construction timber consumption mostly regarding the sawnwood consumption. (table 4). As it was expected all of them are showing quite strong relationship among forest products footprint and sawnwood consumption. This relationship varies in significance starting from Germany with r=0.337 reaching to r=0.889 regarding Lithuania. On the other hand, among the seven countries that were examined only three of

them (Italy, Lithuania and Netherlands) wood panels consumption seems to be related with the footprint. In all the above cases the significance level of the correlations was below 0.05.
The results indicate that production per capita has the strongest relationship with consumption per capita for sawnwood and panels in the examined countries during the studied period. It is indeed not surprising that production would rise with rising demand for wood products. However, the fact that this is somewhat decoupled from changes in per capita GDP in many countries suggests that production could also be driving demand. In other words, it suggests that an increase in domestic production can contribute to increased consumption, and hence an increase in forest footprint. This would belie assumptions that increasing local production will reduce imports, or external forest footprints. Rather it suggests that factors driving internal and external footprints must each be subject to their own systematic examination.
Income plays a smaller role in consumption but not a minor one, particularly in the emerging economies. In most of the countries (Netherlands for both categories and Portugal for sawnwood are excluded) there was a positive correlation between consumption and GDP per capita. However, in a few countries the correlation was negative, while in others GDP seems to not play a significant role in consumption either way, for example in sawnwood consumption in France or for sawnwood consumption and panels in Germany and Ireland.
Finally, most of the examined countries are showing strong significant relationship between the forest products footprint and the sawnwood production, while only in three of them an important relationship between panels consumption and forest footprint is observed. The latter observation, could reveal connections of the apparent consumption of construction timber with the national footprint creation meaning that except sawnwood important quantities of production or imports of wood panels could have contribution to the footprint creation. If we consider the connection between wood panels and furniture industry, seems that furniture industry development plays its role in footprint creation inside and outside of the country (i.e. Italy is one of the biggest producers in the word). This suggestion of course does not cover the subject in total and surly demands further investigation. Even if furniture production motivates footprint creation, other parameters like the percentage of certified wood production that used for furniture production, the national forest products imports policy, the efficiency of production and the origin of imports must be considered.
Categorically, it is important to underline several caveats to the above observed patterns. Firstly, they apply only to the ten case study countries. More such analysis would be needed to assess whether such patterns hold across the rest of Europe. Secondly, this research does not, by itself, enable conclusions about whether more or less domestic production is sustainable from a footprint perspective. This would require, for one, a more holistic material flow analysis which takes into account product substitutions. For example, if increased domestic production leads to increased consumption of construction timber this could reflect an increase in the net ecological footprint, or it could reflect a switch from non-wood to wood building materials and a decreased footprint. Likewise, the study's focus on wood volumes does not address the sustainability of how the wood is produced. It is possible, for example, that increasing domestic production contributes to improved production efficiencies and/or improved local knowledge and engagement in sustainable forest management, both at home and abroad. Europe is relatively well endowed with forests, and it is arguably the environmental and social "quality" of its forest footprint that matters as much as its quantity.

Conclusions

This paper analyzed construction timber (sawnwood and wood-based panels) consumption, production and GDP per capita in ten EU case study countries, ranging from heavily forested, high producing countries to low forest, low producing countries. The volume of domestic production per capita was strongly correlated with consumption per capita in most of the case

studies. The role of GDP per capita was smaller overall, and less consistent within the Western European economies, but does appear to drive demand for construction timber in the eastern European countries examined. From a footprints perspective, this illustrates that increasing domestic production may lead to an increase in a country's total forest footprint. This suggests, in turn, that increasing local production may not reduce a country's imports, or external forest footprint, unless it is accompanied by other changes or policy measures that address total consumption and import activity. Moreover, was confirmed that between the two subcategories of construction timber sawnwood consumption seems to play more important role in footprint creation than wood panels.
The findings in this study are limited to the EU countries analyzed. This, plus the highly dynamic nature of global wood markets and associated socioeconomic and technological contexts, means that these findings should not be used in isolation to investigate the factors that forest products footprint creation extensively. Furthermore, the examination of a single product category – i.e. construction timber – does not allow us draw conclusions about effects on net ecological footprints; rather doing so would require attention to other factors such as net material flows and production substitutions. Nevertheless, what this research does clearly illustrate, is the importance of understanding what shapes the nature and size of ecological footprints. Such understanding is crucial if we are to design effective policies to improve and reduce them.

CHARACTERIZATION OF *POPULUS* HYBRIDS BY THEIR DIFFERENT RESPONSES TO ABSCISIC ACID DURING *IN VITRO* CULTURE

Abstract

The aim of the study was to determine the effect of phytohormone abscisic acid (ABA), known for its accumulation in plants during stress (e.g., drought), on four selected *Populus* genotypes. These represented the crossings of Eurasian aspen with either American aspen (*P. tremula* × *P. tremuloides*; genotypes L191, Wa13, and 174/10) or white poplar (*P. tremula* × *P. alba*; genotype 91/78). Experiments were conducted on clonal *in vitro* cultures through two stages. First, explants – apical shoot segments – were cultured on different media, either hormone-free or enriched with 3 μmol l^{-1} ABA, in darkness (thus, genotype responses to the absence of light were also tested). Afterwards, the apical segments of control and ABA-treated shoots were excised again and transferred onto fresh hormone-free medium under standard light conditions. The results showed that genotype L191 was most negatively affected by darkness and further suppressed by ABA. In comparison to L191, Wa13 was less affected by darkness, but its root formation and development remained suppressed by ABA even during the following subculture on hormone-free medium. Genotype 174/10 developed relatively well in darkness and, among the tested genotypes, was least affected by ABA. Meanwhile, genotype 91/78 showed the most complex response to ABA: it had weaker shoot growth and root development under direct ABA treatment. However, on the fresh hormone-free medium, the ABA-affected 91/78 explants had longer shoots and dominant roots than their counterparts from the control variant. This suggests that, in crossings with aspen, white poplar genes can improve a proper response to stress hormone ABA.

Keywords: *Abscisic acid, Aspen, White poplar, Hybrid tree, Rooting*

Introduction

Because the global resources of fossil fuels are declining steadily, the world-wide interest in fast-growing tree genera, such as willows (*Salix*) and poplars (*Populus*), is increasing and the representatives of these genera are widely used for the establishment of forest plantations aimed at fast biomass production (Rosso *et al*., 2013). In Northern and Central Europe, Eurasian aspen (*Populus tremula*), a native tree species of this region, is often involved in *Populus* breeding and selection programmes (Müller *et al*., 2012). *P. tremula* hybridization with, e.g., American aspen (*Populus tremuloides*) and white poplar (*Populus alba*) can result in genotypes with high growth rate and biomass productivity (Niemczyk *et al*., 2019). Hybridization between *P. alba* and *P. tremula* occurs also naturally, resulting in the hybrid poplar species *Populus* × *canescens* (Santos-del-Blanco *et al*., 2013). Poplar species, including *P. tremula*, are characterized by high intraspecific genetic variation (Zhang *et al*., 2015); therefore, even genotypes derived from a same interspecific crossing combination can be considerably different from each other and the use of different species further increases variability among hybrid *Populus* genotypes. In the context of this variability, it is important to select *Populus* genotypes with potentially best phenotypic qualities.

One of the most important characteristics of promising tree genotypes would be their ability to maintain growth after stress. The current knowledge about the regulation of plant stress

responses, as summarized, e.g., by Brunner *et al*. (2015), indicates that plants, once under stress conditions, accumulate higher levels of the hormone abscisic acid (ABA). This usually leads to the above-ground growth inhibition, helping to save energy and nutrient resources. Although ABA, as an inducer of stomatal closure (Liu *et al*., 2001), is especially important under drought stress, this hormone enables plants to survive under various sorts of unfavourable conditions, including cold (Bertrand *et al*., 1997), heat (Talanova *et al*. 2006), and increased concentration of salt or toxic materials (Hsu and Kao, 2005). Since one of the primary steps in *Populus* selection would be the identification of genotypes with a potential to continue growing after encountering unusual or unfavourable environmental conditions, the ability of a particular genotype to restore its growth parameters after the treatment with ABA could be suggested as one of the early test criteria.
Accordingly, the present *in vitro* study tested four hybrid *Populus* genotypes, derived from the crossing combinations *P. tremula* × *P. tremuloides* and *P. tremula* × *P. alba*, for their responses to ABA. The initial experiments involved culturing of *Populus* explants on the hormone-free or the ABA-supplemented medium variants in darkness because of the recorded susceptibility of ABA molecules to light-induced destruction (Wenjian *et al*., 2013). The culture of explants on the hormone-free medium in light was involved as a separate experimental treatment at this stage in order to see how darkness itself affects the development of the studied genotypes. Further, the second stage of the study was designed to identify the differences among the *Populus* genotypes in respect of their ability to recover after ABA treatment and, for this aim, the explants from both the control and the ABA-treated variants were transferred onto a fresh hormone-free medium.

Material and Methods

The data on the four *Populus* genotypes involved in the study are given in Table 1. The experiments were conducted on the clonal shoot cultures of these genotypes, maintained *in vitro*. In both the pre-experimental and the experimental treatments, *Populus* shoots were cultured on the solid Murashige and Skoog (MS) nutrient medium containing 20 g l^{-1} sucrose and 4 g l^{-1} Gelrite (commercial gelling agent based on gellan gum), with the pH value set at 5.8. The medium, used for the multiplication of shoots before the start of experiments, was supplemented additionally with 0.6 mg l^{-1} 6-benzylaminopurine and 0.1 mg l^{-1} 1-naphthylacetic acid. The medium and its additional components, including the hormone ABA used for the experiments, were purchased from Duchefa Biochemie, The Netherlands.

Table 1. *Populus* genotypes used in the experiments of the study

Genotype	Crossing combination	Place of origin
91/78	*Populus tremula* × *P. alba*	Forest Research Institute, Poland
L191	*Populus tremula* × *P. tremuloides*	Thünen Institute, Germany
Wa 13	*Populus tremula* × *P. tremuloides*	Thünen Institute, Germany
174/10	*Populus tremula* × *P. tremuloides*	Thünen Institute, Germany

The MS nutrient medium used for the first stage of experiments was either hormone-free (for control) or supplemented with 3 μmol l^{-1} ABA. 10-mm-long apical shoot segments cut from the *in vitro*-grown *Populus* shoot cultures were used as explants. These were placed in Petri dishes, 13 mm of height and 55 mm of diameter, and cultured for three weeks in darkness. Each Petri dish contained 12 ml of nutrient medium and five explants. The additional, third, experimental variant at this stage contained explants cultured on the hormone-free medium but under 16-hour white-light photoperiod. After the period of three weeks, both the control and the ABA-treated shoots, cultured in darkness, were used to prepare new 10-mm-long apical explants. These were transferred onto the fresh hormone-free medium and cultured for subsequent six weeks in glass jars under 16-hour white-light photoperiod. Each jar, 75 mm of height and 70 mm of diameter, contained 30 ml of nutrient medium and four explants.

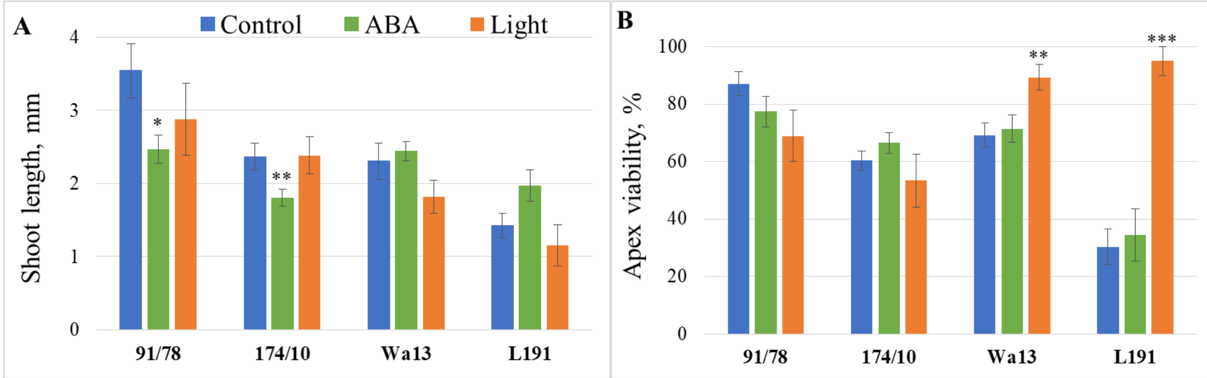
Each experimental variant (genotype × treatment) consisted of three replicates, 20-25 explants per replicate, and these were organized in a completely randomized design. The results presented in this study include the following parameters: the rate of explants with green shoot apex (apex viability, %), the increase of shoot length starting from the original 10 mm (shoot length, mm), and the rate of explants with visible roots (rooting, %). Because of the low rooting rate under direct ABA treatment, the data on root length are given only for the second experimental stage. These data include the length of the largest root of an individual explant and the total root length per explant. For the comparison of the obtained results, a two-tailed Welch's *t*-test (Welch, 1947) intended to compare samples with possibly unequal variances was performed to calculate the probability that the means of the different variants are equal.

Results and Discussion

The results of the first experimental stage are shown in Figure 1. On the hormone-free medium, the differences among the four genotypes in shoot elongation both in darkness and in light (Figure 1A) were closely related to the ability of shoot apex to remain green in darkness (Figure 1B). The genotype 91/78, which, differently from the other three genotypes, was obtained after crossing of *P. tremula* with *P. alba* and not with *P. tremuloides*, had the highest average shoot length increase both in darkness and in light as well as the highest shoot apex viability rate in darkness (87.1±4.3%). 91/78 contrasted most strongly with the genotype L191 which had the lowest average shoot length increase both in darkness and in light as well as the lowest shoot apex viability rate in darkness. The particularly low shoot apex viability rate of L191 in darkness (30.4±6.2%) contrasted strongly with the same genotype's high rate of shoot apex viability in light (95.0±5.0%). Another genotype which had a significantly lower shoot apex viability rate in darkness than in light was Wa13 but the difference here was much less dramatic than in L191. In the other two genotypes, 174/10 and 91/78, the shoot apex viability rate in light was not higher than in darkness (Figure 1B).

Regarding the light-dependent patterns of adventitious rooting, the genotypes 174/10 and Wa13 (both *P. tremula* × *P. tremuloides*) had much higher rooting rates in darkness than in light (Figure 1C). The negative effect of light on the rooting of *P. tremula* × *P. tremuloides* clones is also reported by Stenvall *et al.* (2005) who performed experiments on root cuttings. This negative response of *P. tremula* × *P. tremuloides* to light was in strong contrast to the observation made on the genotype 91/78 (*P. tremula* × *P. alba*) which had a 2.4-fold higher rooting rate in light than in darkness (Figure 1C).

As it is shown in Figure 1A, the hormone ABA decreased shoot growth significantly, although not dramatically, in the genotypes 91/78 and 174/10 (to 69.7% and 76.0% of the control variant, respectively). ABA did not affect the viability of shoot apex itself in any of the tested genotypes (Figure 1B). The most significant effect of ABA during the first experimental stage was found in respect of rooting whose rate was decreased by this hormone in all the studied genotypes (Figure 1C). In the genotype 174/10, the negative effect of ABA on rooting was relatively slight but, in the other genotypes, it ranged from an 8-fold decrease (in 91/78) to even a 16.7-fold decrease (in Wa13).



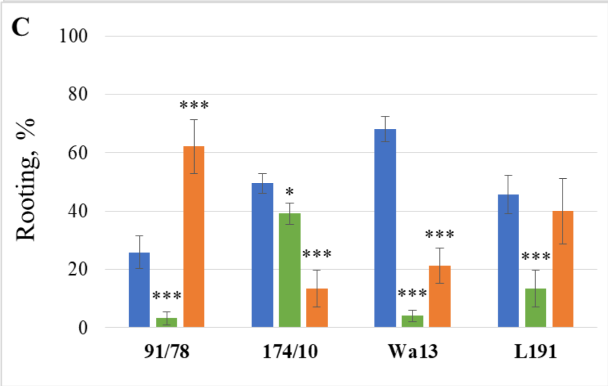


Figure 1. Characterization of the shoot explants from four *Populus* genotypes after three weeks of *in vitro* culture: A – shoot length; B – rate of explants with green shoot apex; C – rate of explants with adventitious roots. Different culture conditions are denoted: "Control" – hormone-free medium, darkness; "ABA" – medium with 3 µmol l^{-1} of abscisic acid, darkness; "Light" – hormone-free medium, 16-hour photoperiod. Significant differences between the control and the other two treatments are indicated: *P < 0.05, **P<0.01, *** P <0.001.

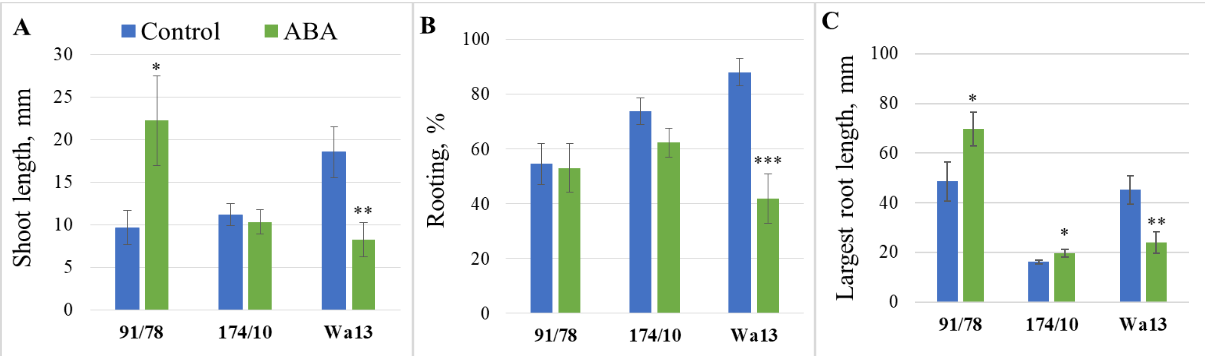
After the first experimental stage, the viable shoots were used for the preparation of new explants that were transferred onto the fresh hormone-free medium in jars for subsequent observation. This second experimental stage involved only three of the four initial genotypes, since the particularly low shoot apex viability of the genotype L191 explants cultured in darkness did not allow to continue with this genotype into the second stage. The results obtained with the three remaining genotypes during the second experimental stage are given in Figure 2. The major contrast in the development after the ABA treatment was observed between the genotypes Wa13 (*Populus tremula* × *P. tremuloides*) and 91/78 (*Populus tremula* × *P. alba*). The Wa13 explants taken from the ABA-supplemented medium were 1.9 times shorter than their counterparts from the hormone-free medium (Figure 2A) and had a 2.1 times lower rooting rate (Figure 2B). The root length in Wa13 was also significantly decreased by the previous ABA treatment (Figure 2C-D). Meanwhile, the second genotype of *P. tremula* × *P. tremuloides* – 174/10 – remained almost unaffected by the previous ABA treatment, except a slight (1.2-fold) increase in the average largest root length (Figure 2C).

In contrast to Wa13, the genotype 91/78 (*P. tremula* × *P. alba*) was affected positively by the previous ABA treatment. Here, the average shoot length after the ABA treatment in the previous subculture was 2.3 times higher than in the control variant (Figure 2A). The average largest root length was also affected positively by the previous ABA treatment, with a 1.4-fold increase in comparison to the control variant (Figure 2C).

The obtained results indicate that the genotype 91/78, derived from a crossing of aspen with white poplar (*P. alba*), had the most desirable response to the exogenously applied stress hormone ABA among the studied *Populus* genotypes. There are reports indicating a superior resistance, for example, to toxic stresses of both *P. alba* (Castiglione *et al.*, 2009) and its hybrids with *P. tremula* (Bittsánszky *et al.*, 2009). Interestingly, in the report by Bojarczuk

(2000), it was found that microcuttings of hybrid poplar *P. tremula* × *P. alba* had better developed root system in the substrate with aluminium (a toxic factor) in the case they were grown previously on the *in vitro* medium with the same toxic factor. As ABA is known as one of the most important signals that enables poplars to cope with the environmental toxicity (Shi *et al.*, 2019) and other abiotic stresses (Arend *et al.*, 2009), the ability of the genotype 91/78 to increase its growth during the subsequent culture stage after ABA treatment makes this genotype particularly interesting for further studies aimed at the selection of promising *Populus* genotypes.



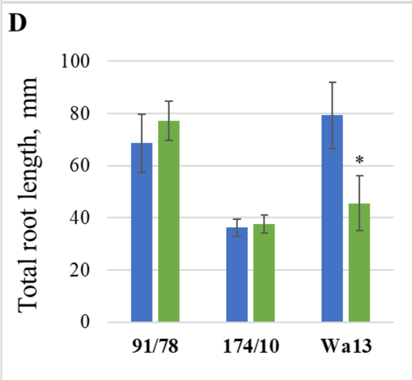


Figure 2. Characterization of the morphogenesis on the shoot explants from three *Populus* genotypes after six weeks of *in vitro* culture under 16-hour photoperiod: A – shoot length; B – rate of explants with adventitious roots; C – largest root length; D – total root length. During the previous subculture, the donor shoots used for explant preparation were cultured in darkness either on the hormone-free medium ("Control") or on the medium with 3 µmol l^{-1} of abscisic acid ("ABA"). Significant differences between the control and the ABA treatments are indicated as follows: *P < 0.05, **P<0.01, *** P <0.001.

Conclusions

Among the studied *Populus* genotypes, L191 (*P. tremula* × *P. tremuloides*) was most negatively affected by darkness and further suppressed by ABA. In comparison to L191, Wa13 (*P. tremula* × *P. tremuloides*) was less affected by darkness, but its root formation and development remained suppressed by ABA even during the following subculture on hormone-free medium. Genotype 174/10 (*P. tremula* × *P. tremuloides*) developed relatively well in darkness and, among the tested genotypes, was least affected by ABA. Meanwhile, genotype 91/78 (*P. tremula* × *P. alba*) showed the most complex response to ABA: it had weaker shoot growth and root development under direct ABA treatment but, on the fresh hormone-free medium, the ABA-affected 91/78 explants had longer shoots and dominant roots than their counterparts from the control variant. This suggests that, in crossings with aspen, white poplar genes can improve a proper response to the stress hormone ABA.

Abstract

Non-timber forest products (NTFPs), also known as non-wood forest products (NWFPs), minor forest produce, special, minor, alternative and secondary forest products, are useful substances, materials and commodities obtained from forests which do not require harvesting (logging) trees. NTFPs is an important source of food and income. Several million households world-wide depend heavily on NWFPs for subsistence or income. Some 80 percent of the population of the developing world use NWFPs for health and nutritional needs. NWFPs have also attracted considerable global interest in recent years due to the increasing recognition of their contribution to environmental objectives, including the conservation of biological diversity. It is an important "branch" of forest management which not include the harvesting. Due to the fact that Romania has a wide variety of relief forms, numerous NWFPs can be found on her territory, the most important ones being forest fruits. Across the country, the distribution of NWFPs is not so uniform. These are rich in vitamins and have antioxidant properties, being used in alimentation, medicine and the cosmetic industry. The present article exposes the most representative forest fruits from Satu Mare County. Their classification is also realized based on an analytical hierarchy that takes into account 19 well-established criteria.

Based on an analytical hierarchy, their classification it was been realized by 19 well-established criteria. The abundance was dominated by fruits like sweet chestnuts, raspberries and wild pears.

Key words: *analytical hierarchy process, forest fruits, harvesting period, perishability, NTFPs*.

Introduction

During the past decades, the role of the forest has changed in Europe. NTFPs obtained from plant resources, including seeds, flowers, fruits, leaves, roots, bark, latex, resins and other non-wood plant parts, have gained much attention in conservation circles (Ticktin, 2004). Besides wood, its principal source, non-timber resources have become of interest. According to the Food and Agriculture Organization (FAO), the term which characterises these resources is "non-timber forest products" (NWFPs). The FAO organization adopted the working definition that: "Non-wood forest products consist of goods of biological origin other than wood, derived from forests, other wooded land and trees outside forests". NWFPs exclude timber and that the product, benefit or service should come from the forest (Wong *et al.*, 2001). Non-timber forest products (NTFPs) have been harvested by human populations for subsistence use and trade over thousands of years. FAO estimates that about 80% of populations from developing countries use NWFPs in food and medical industries (http://www.fao.org/).

The scope of this present paper is to identify the most important forest fruits from Satu Mare County. From a geographical point of view, Satu Mare County is situated in North-Western Romania. It was established in 1968 by the territorial reorganization of the former Maramures Region (from Satu Mare, Carei and Negresti-Oaş districts). Most of the territory of today's county was part of Satu Mare County (interwar) and of Satu Mare County (antebelic) respectively (https://ro.wikipedia.org/). The county seat and cultural, educational and economic center of the county. Its estimated surface reaches 4.418 km² (1,9 % from national territory). Land use includes : 72 % agricultural territories, 18 % forests, 3 % rivers, 7 % another surfaces (https://ro.wikipedia.org/).

Fig.1 Location of Satu Mare County, source: https://www.wikipedia.org/

The following forest fruits can be found in Satu Mare County: rosehips (*Rosa canina* L.*)*, raspberries (*Rubus idaeus* L.), black shock (*Sambucus nigra* L.), blackthorns (*Prunus spinosa* L.*)*, hawthorns *(Crataegus monogyna* L.*)*, horns (*Cornus mas* L.), sweet chestnuts (*Castanea sativa* Mill.) and wild pears (*Pyrus pyraster* L.) (Vasile *et al.*, 2016).

Material and methods

Thomas Saaty has created during the last several decades, an analysis decision model based on multiple criteria. The Analytical Hierarchy Process (AHP) was used in taking decisions in numerous domains (Saaty, 2008). Thus, the same process was used in determining the most important forest fruits from Satu Mare County. Expert Choice Desktop (v. 11.5.1683) was used an analysis software. The following criteria were taken into consideration for the analysis of the main forest fruits from Satu Mare County: harvesting period, harvested quantity by one worker in 8 hours, harvesting cost, harvesting knowledge, tools needed for harvesting, complexity of harvesting process, the development of the harvesting process, recognition knowledge, distribution range, biotic threats, abiotic threats, perishability, market potential, market demand, "celebrity" of the product on the market, the price of raw product, the price of the derived product, portfolio of derived products and transport from the harvesting point to the storage centre. These criteria have also been used in other similar studies from different counties such as: Maramureș (Enescu *et al.*, 2017), Gorj (Vechiu *et al.*, 2018), Prahova (Enescu *et al.*, 2018), Timiș (Enescu *et al.*, 2018) and Bihor (Timiș-Gânsac *et al.*, 2018).

Results and discussion

In the (Table 1.) were presented the 19 criteria taken into consideration for analysing the most important forest fruits from Satu Mare County. The criteria have been approved by specialists.

Table 1. AHP alternative ranking

Criterion		Berries							
		Rosa canina	*Crataegus monogyna*	*Rubus idaeus*	*Sambucus nigra*	*Prunus spinosa*	*Cornus mas*	*Castanea sativa*	*Pyrus piraster*

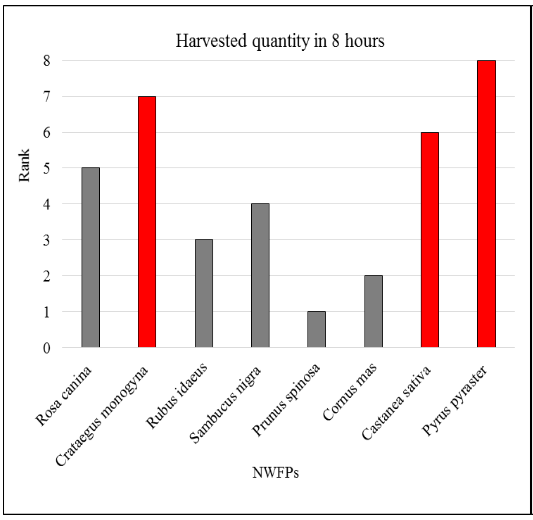
The harvested quantity of wild pears, hawthorns and sweet chestnuts within 8 hours is larger in comparison with rosehips, black shocks and raspberries (Fig.2). Furthermore, the harvesting cost was bigger in the case of wild pears, rosehips and sweet chestnuts (Fig.3). On the other hand, raspberries, wild pears and black shocks are the most perishable forest fruits (Fig.4).



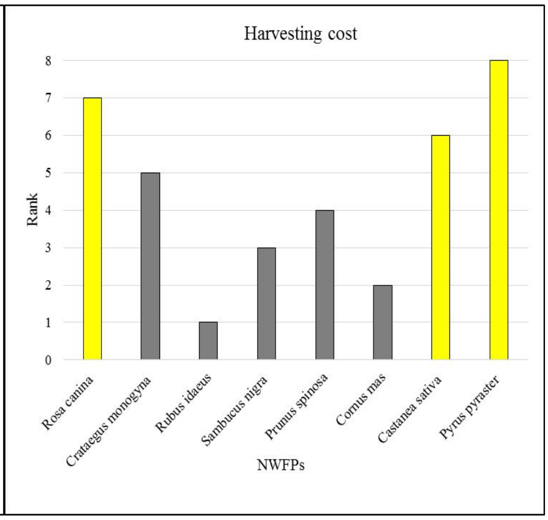


Fig.2 Rank of the harvested quantity in 8 hours Fig.3 Rank of harvesting cost

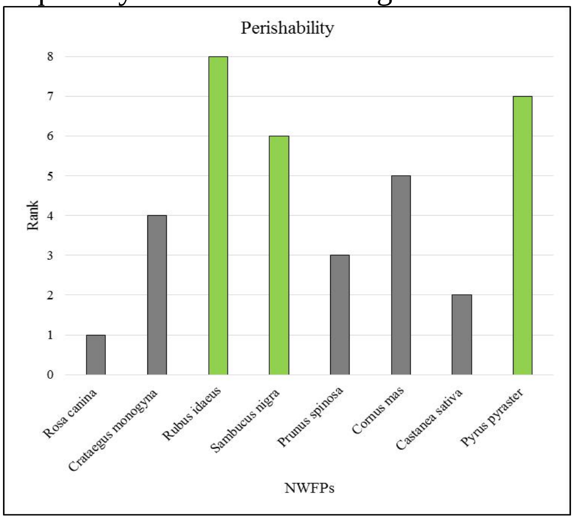

Fig.4 Rank of perishability

The next figure presents the presence of each species through the Expert Choice Desktop software (v. 11.5.1683).

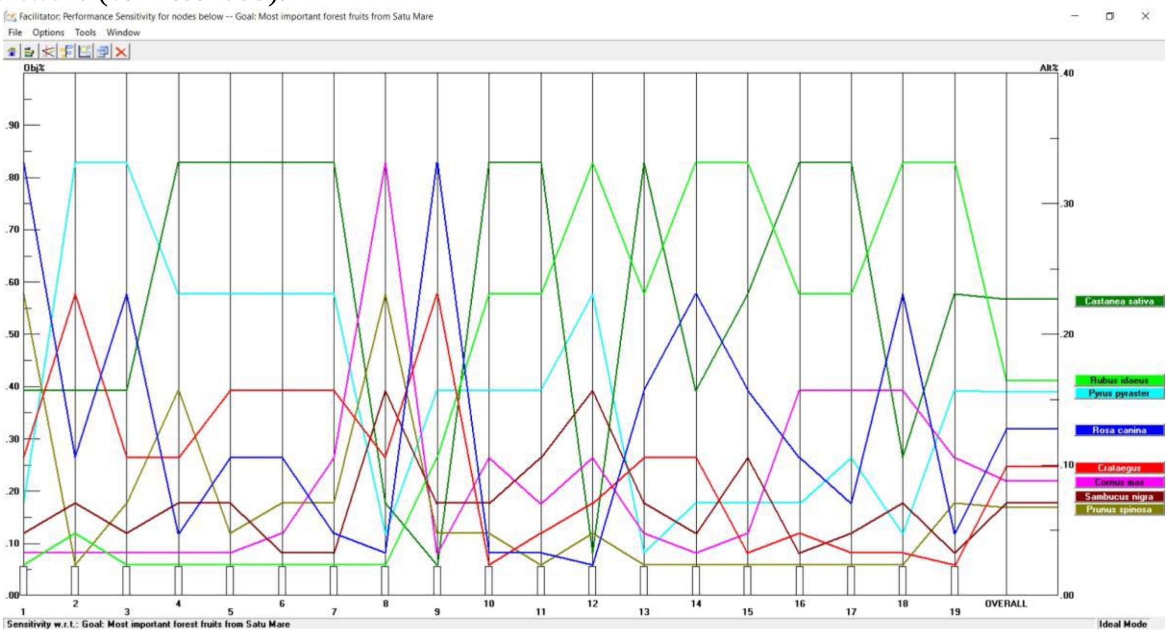

Fig. 5 Ranking of the eight forest fruits

Based on this software program, the most popular and requested forest fruits are sweet chestnuts, raspberries and wild pears (Fig.5). The most important species will be short described in the rows below following their importance in different domains.
Castanea sativa Mill. *(C. vesca* Gaertn.). The food industry uses aproximatevely 7000 t/year of chestnuts in the production of chestnut purée, marron-glacé, etc. The shell as a waste product, which represents ~10% of the weight of whole chestnuts is used as fuel (Vázquez, G. et al., 2008). Wood is of superior quality, comparable to that of oaks. Duramen is very well represented, brown-dark, relatively heavy and hard. It can be used in the furniture industry as well as for parquet, friezes, wainscotings. It is also used for construction (Şofletea and Curtu, 2007). At the same time, chestnut is highly appreciated for its edible, highly nutritious fruit. Contains starch, glucose, sucrose, dextrin, vitamin. By processing, they produce spirits, sugar, oil etc (Şofletea and Curtu, 2007).
Rubus idaeus L. *Rubus idaeus* is part of *Rubus* Genus, subfamily *ROSOIDEAE* FOCKE. By combining gas chromatographymass spectrometry it will be obtain the volatile components of fresh wild raspberries. They were found 75 components, which coresponding to about 64 ppm raspberry oil obtained in the press juice (Honkanen *et al*., 1980).
Fruits are apocarpic, multiple and constitute a globular polidrup, mature red, succulent, sweet. Raspberry is an indicator of rich soil, well supplied with water and nitrogen. He is fructifing abundantly, especially in the light (Şofletea and Curtu, 2007). Fruits are used in the food industry: juices, jams, syrups, etc.
Pyrus pyraster (L.) Burgsd. belong to the plant family Rosaceae. *Pyrus pyraster* does not occur naturally only in the north European countries. Wild pear are autochthonous in several European countries intensive conservation measures are still lacking with the exception of Germany (Turok *et al.*, 1998). The wood is beautifully colored, red-brown, very dense, homogeneous, hard, resistant. It polishes beautifully and is appreciated for sculpture, handicrafts, musical instruments. Fruits are consumed by wild animals. The fruits are obovoidal or globular, stony, dark green to brown, with persistent calyx, astringent (Şofletea and Curtu, 2007).

Conclusions

Satu Mare County has a wide range of forest fruits on its territory. With the help of the analytical hierarchy based on the criteria taken into account, the most representative forest fruits from this region are: rosehips (*Rosa canina* L.*)*, raspberries (*Rubus idaeus* L.), black shock (*Sambucus nigra* L.), blackthorns (*Prunus spinosa* L.*)*, hawthorns *(Crataegus monogyna* L.*)*, horns (*Cornus mas* L.), sweet chestnuts (*Castanea sativa* Mill.), wild pears (*Pyrus pyraster* L.). and others. Based on Expert Choice Desktop software, the third species are the most representative: sweet chestnuts (*Castanea sativa* Mill.), raspberries (*Rubus idaeus* L.) and wild pears (*Pyrus pyraster* L). Forest fruits dispose of necessary conditions for growth and development because of the fact that the region presents different relief forms which comply with the ecological requirements of the species.
Furthermore, it was observed that most species originate from hills and plains, but rarely they are rising also in the montain zone, until altitude reach 700-800 metres, where the climate is warmful and the humidity is lower than 50%. As such, specialists should take into account the areas populated with all these species and to try different methods for conserving and extending them.

Acknowledgements

The authors would like to thank Mr. Cristian Mihai Enescu (Faculty of Agriculture Bucharest) for his support in analysing the data.

Abstract

The main goal in the sustainable forestry is to achieve healthy forest stands which will be passed on to the next generations. Healthy ecosystems and economies rely on high-quality forests. Massive forest decline has occurred in many countries in the last several decades caused by high-number of pest infestation induced by draught and climate change. After the trees have been already physiologically stressed, pests come as the secondary infestation. Many forest pests are capable of devastating the entire forests. In the forest health protection, the key of success is to prevent major pests to breed in high number, as well as early detection of symptoms invisible to the naked eye. The object of study chosen for the application of the multispectral sensor mounted on unmanned aerial system (UAS), were coniferous forest stands, located at Mt. Kopaonik, W Serbia. Utilization of the multispectral imagery have provided us with sufficient information on the forest health and vigor. This was the first application of 5-sensor high-resolution multispectral imagery for the identification of stress of forests in Serbia. Through applications of algorithms and vegetation indices, it was possible to identify not only the dead trees in the remote and hard-to-reach areas, but also the trees which were still physiologically active, but possibly threatened by pests, although without any visible signs of health problems. The results of the study proved that the use of the multispectral sensor and small UAV has in early detection of stress for purpose of improving the health of forest ecosystems were justified.

Keywords: *Remote sensing, Forest protection, Early detection, Forest pests, Multispectral camera.*

Introduction

Due to the climate changes, extreme climate conditions, and extended periods of drought, many forest stands have been diagnosed with a decline of health and productivity. As a modern phenomenon, desiccation of mainly autochthonous spruce stands is present in most countries of Central and Southeastern Europe (Tabaković-Tošić, Milosavljević, 2018). Classified as a national park, Mt. Kopaonik, with over 1600 plant species and its valuable coniferous forest was of special interest. It is situated in western Serbia, with the highest peak of 2017 meters above sea level, and the total area of the national park of 121.06 km^2. Mt. Kopaonik has a subarctic climate, with snow season lasting from November to May. In spite of abundant amounts of snow, the latest observations showed many issues with mortality of large areas of native woodland. The physiological stress caused by drought made individual conifer trees and entire areas suitable for pest infestation which furthermore caused devastation of wide areas. Many of those areas on Mt. Kopaonik suffered from both drought and secondary pest infestations.

During 2018. salvage logging was done in the areas identified with total loss of vitality of groups of trees, and in areas infested with two species of bark beetle - *Pityogenes chalcographus* L. and *Ips typographus* L. In total 11,330 m3 of wood was removed.

Another important effect bark-beetle infestation is the production of fuel for wildfires. The changes in foliage chemistry and reduction of moisture increase flammability of the tree and reduces heat requirements for ignition (Jolly *et al.*, 2012).
Use of modern technology would allow precise identification of areas not only already infested, but also the areas prone to the infestation. This information would increase the effectiveness of prevention measures. Two study areas were chosen for this research.
The purpose of the study was testing the combination of small Unmanned Aerial Systems (sUAS) and ground-truthing for early detection and identification of apparently healthy, and physiologically active trees, that may be prone to the secondary infestation. This was the first application of sUAS in combination with 5-band multispectral imagery in forestry in Serbia.

Materials and Methods

Remote sensing approach chosen for study areas consisted of multispectral and RGB sensors mounted on small Unmanned Aerial Systems. The multispectral sensor was MicaSense RedEdge M. This multispectral sensor consists of 5 individual sensors, each capable of taking images in a single discreet narrow band. Medium wavelengths for sensors are: Blue (475nm), Green (560 nm), Red (668), Red Edge (717nm), Near Infrared (840nm). The resolution of each sensor is 1.2 Mpix. The multispectral sensor is also equipped with its own GPS and magnetometer module, and Downward Light Sensor for correction of sensor exposure during the flight.Before and after each flight, the calibration images were taken by a multispectral sensor. Images of calibration panel with predefined spectral values are used during the processing of the images so that sensitivity to different light conditions of reflectance values in the resulting orthomosaics are minimal. All images used from the multispectral sensor were in 16-bit TIFF format. RGB sensor has a standard Bayer pattern sensor for taking images in the visible part of the electromagnetic spectrum. It has a resolution of 20 Mpix, and the sensor was mounted on 3-axis gimbal. Small UAS used as a carrier platform for both sensors was quadcopter DJI Phantom 4 Pro. Both sensors were mounted simultaneously while sUAS was airborne. Flight altitude of first flights was 100m above ground level (AGL), above the point of take-off, while the second area was imaged from 80m AGL. The altitude remained constant throughout the flight – aircraft did not follow terrain change. The first study area was mapped in automatic flight mode via 3rd party professional UAS surveying app Datufly, while the second flight was flown manually, due to the combination of environmental factors – flight altitude, the height of trees, high wind velocity, and area of coverage.
Imaging was done in the middle of the April, and there were patches of snow still present on the ground but canopies were 100% clear and visible. Processing of the images was done in professional photogrammetry software Agisoft Metashape

Rationale

Multispectral imaging has been in use for over 60 years in agriculture and precision agriculture. Reflectance values have been related to vegetation characteristics such as plant biomass or fraction of intercepted photosynthetically active radiation (Barnes, Clarke, Richards, 2000). With recent improvement and development of technologies, the sensors became more compact, and in combination with small UAS, it provided the opportunity to transfer knowledge and technology into other industries. In forest inventory mapping high-resolution multispectral imagery became an essential, and an often critical tool for effective forest management (Moskal *et al*., 2002). Many technologies and innovation transcended from agriculture to forestry. The same vegetation indices, developed for estimation and quantitative evaluation of crop health, are also used in forestry.

Since bark beetles can affect large spots in hard to reach areas, remote sensing is the most promising way to cover large areas, identify the potential infestation, measure it and provide information for future decision making (Stoyanova *et al.*, 2018).
Vegetation indices (VI) are a mathematical algorithm based on digital brightness (spectral) values. Those values are added, subtracted, divided and multiplied to yield a single value that indicates the amount of vigor of vegetation in pixel. High values of VI corresponds with the areas covered by a substantial amount of healthy vegetation (Cambell, Wynne, 2011).
High-resolution multispectral imaging is the latest tool used in forestry to prevent wide area pest infestation and devastation. Five narrow band individual sensors allowed the application of multiple vegetation indices:

- NDVI – Normalized Difference Vegetation Index
- NDRE – Normalized Difference Red Edge

NDVI is the most widely used VI. It represents the band ratio of two spectral behaviors with inverse relationship – absorption of Red light by chlorophyll, and strong reflectance of Near-Infrared light by mesophyll tissue. Physiologically active and grooving plants have high values of NDVI, whereas bare lands, water, snow, man-made objects, and dry vegetation have low index values (Cambell, Wynne, 2011).
NDVI values are calculated through formula:

$$\frac{R_{NIR} - R}{R_{NIR} + R}$$

R_{NIR} – Reflectance values in Near Infrared band
R_{RED} – Reflectance values in Red band
NDRE is the modification of the NDVI which uses Red Edge portion of the electromagnetic spectrum instead of RED light. Due to the longer wavelength, it is capable of penetrating deeper in the canopy, thus providing more relevant information on the health status of a plant, and it is more sensitive to the chlorophyll status than indices relying on RED. Using the information from Red Edge part of the spectrum has the potential to significantly improve forest stress monitoring (Eitel *et al.*, 2011) and NDRE is potentially the best index for forest stand assessment since it is less sensitive to the changes in different study area parameters (Modzelewska *et al.*, 2017)
NDRE values are calculated through formula:

$$\frac{R_{NIR} - R_{EDGE}}{R_{NIR} + R_{EDGE}}$$

R_{NIR} – Reflectance values in Near Infrared band
$R_{RED\ EDGE}$ – Reflectance values in Red Edge band
Both indices have a range of values from -1 to +1. Vegetation index values are represented through color-coded thematic maps for easy visualization. To increase visibility HEAT palette was used with high levels of the index in red color, while low levels were in blue.

Study areas

For this research two study areas were chosen. Before the application of sUAS, both areas were surveyed by personnel of the Institute of forestry, and health status of each area was diagnosed by routing and random sampling methods.
The first study area (management unit Samokovska Reka, forest compartment 114/d) had a total area of approximately 35 ha. It consists of tall spruce trees of various ages. Maximum terrain altitude was 1530 m a.s.l., while the minimum was 1440 meters. The forest was predominantly coniferous, with no, or very little signs of desiccation. Majority of forests were situated in the lower parts of the study area. There was no predefined area of interest, the entire area was imaged with both sensors and multiple vegetation indices we applied.

The second area (management unit Samokovska Reka, forest compartment 95/b) had a total area of approximately 2.3 ha, and altitudes form 1540 – 1570m a.s.l. This area was heavily affected with infestation with a lot of dry and fallen trees, surrounded by apparently healthy vegetation.
Imaging of both study areas took approximately 30 minutes in total.

Results and Discussion

The products of the imaging and processing were dense point cloud, digital elevation model (DEM), and ortho-mosaics. We have produced both RGB (Figure 1) and vegetation indices (Figure 2 and Figure 4) orthomosaics. High resolution of the images provided orthomosaics with a resolution of approx. 3.4 cm/pixel for RGB and 8 cm/pixel for multispectral. This allowed the application of indices not only on tree level but also on parts of the trees.
Mapping of both study areas showed several areas with daed trees which are easily visible even in the RGB orthomosaic. However, the purpose of this research was not the identification of already dead trees, but the identification of the areas that will present the future potential of infestation. Also, the areas of dry trees provided a good starting point for ground-truthing. Especially interesting were areas in the vicinity of dry trees with individuals and groups of trees with medium to low VI values.

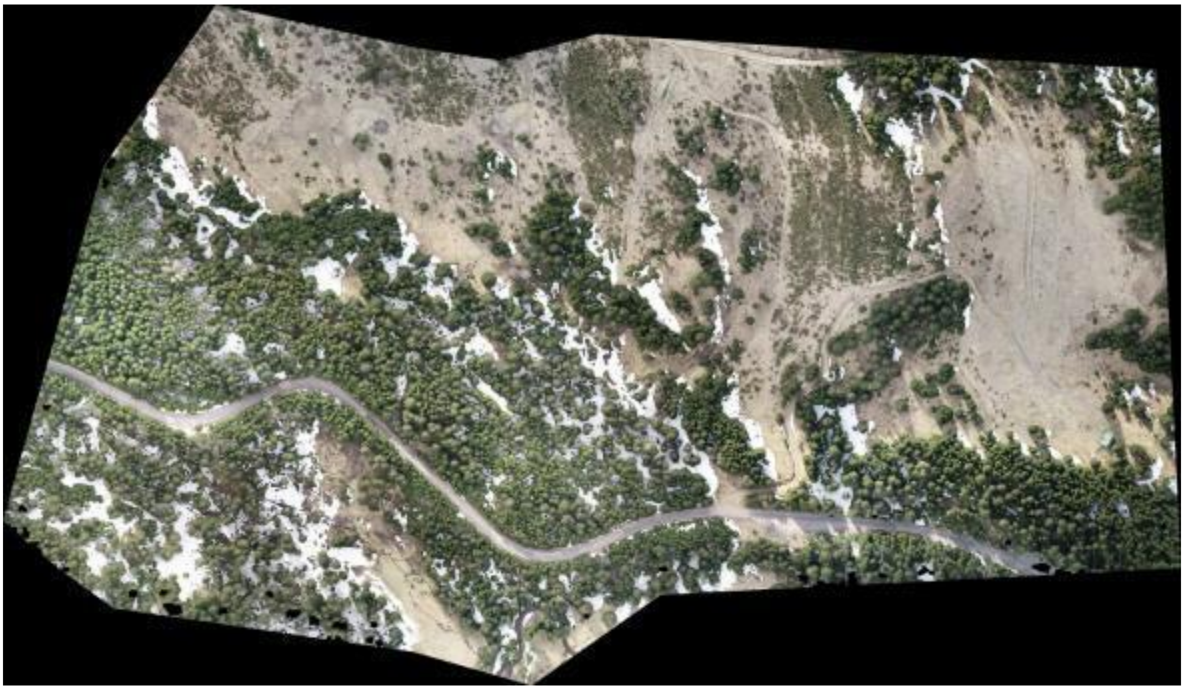

Figure 1. Study area 1 – RGB orthomosaic

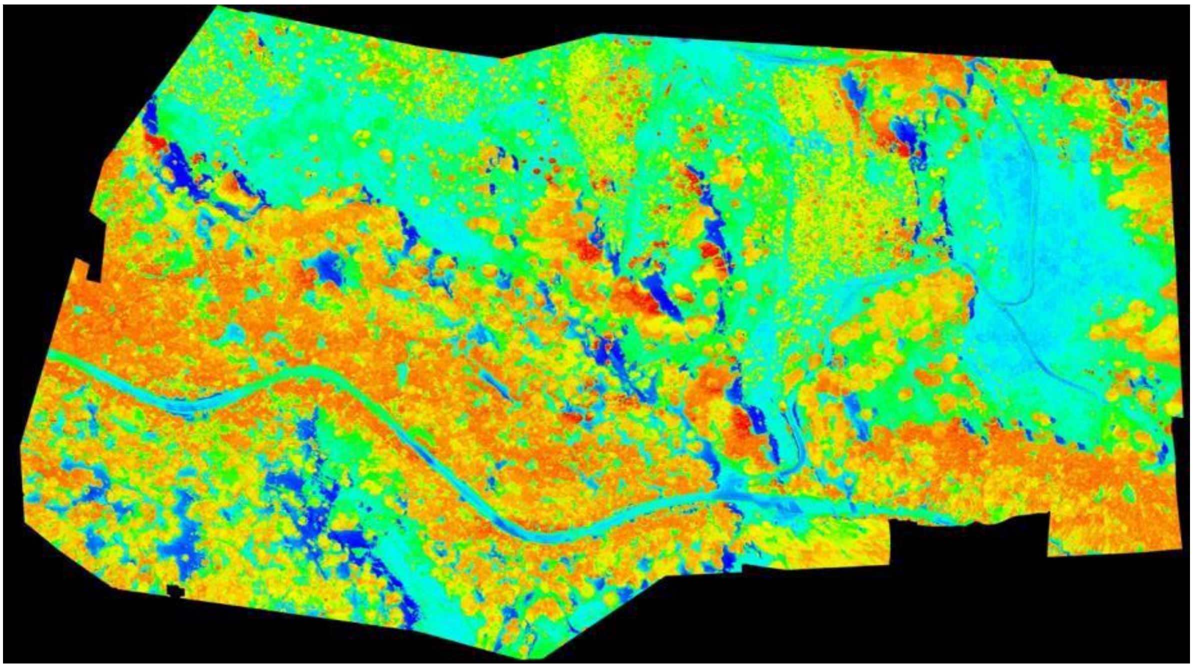

Figure 2. Sturdy area 1 – NDVI index

Application of the NDVI vegetation indices showed several areas with lower index values that in the RGB orthomosaic looked healthy and physiologically active (Figure 3). Aerial imaging also showed exact locations of dead and fallen trees, which have remained in the forest. Terrestrial (*in-situ*) observations confirmed the poor state of the stand with a high number of dying trees, with the presence of fungi, and old entering and exiting holes of bark beetle. To the poor health of the forest has also contributed poor extraction of the dead and fallen trees which could serve for development and rapid multiplication of highly aggressive xylophagous insect pests (Dimitrov *et al.*, 2019).

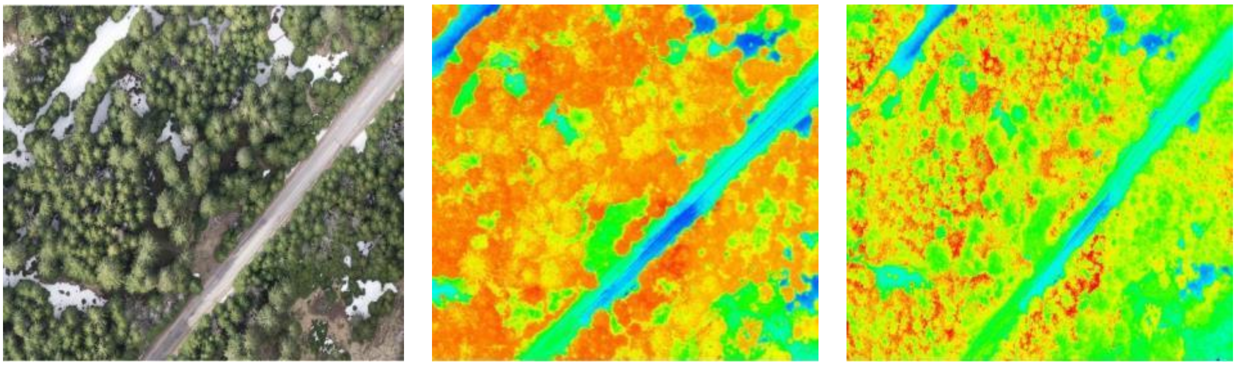

Figure 3. Study area 1 – comparison of same area in RGB, NDVI, and NDRE maps

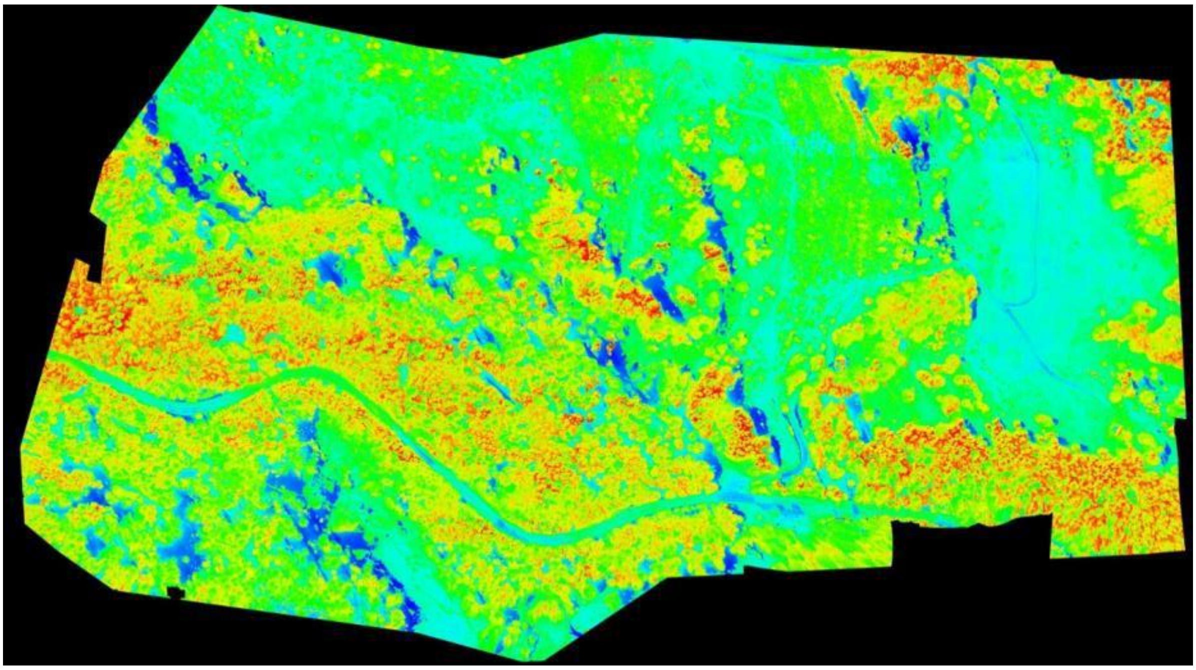

Figure 4. Study area 1 – NDRE index

Application of NDRE vegetation index confirmed NDVI map, but it also showed more dramatic status with more pronounced low levels of the physiological activity of vegetation as shown in Figure 5. Since this was the first imaging early in the spring, another imaging in the summer should add more data to this first map. It should also provide more information on the physiological activity of the trees. NDRE showed many areas and trees with low index values. Regular imaging and application of NDRE index have the potential for providing relevant information on the health status of the forest throughout the year. Especially since indices relying on NIR and RED tends to saturate at medium to fully developed canopies (Xie Q *et al*., 2018).

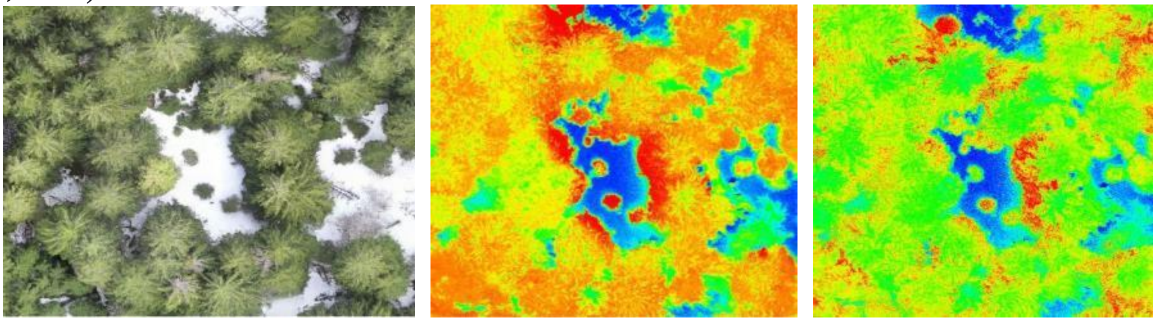

Figure 5. Part of study area 2 – from left to right - RGB, NDVI, NDRE

Conclusion

Use of small unmanned aerial vehicles equipped with RGB and multispectral sensors are a fast and easy tool for acquiring the high amount of precise information which can be used for assessment of health status of vegetation, identification, and geolocation of the problematic areas. This kind of imaging can be used as a foundation for further land cover classification for field-work and forest care planning. This kind of high-resolution imaging provided high levels of details, in 2D and 3D color-coded multispectral vegetation indices. All processing and assessment were performed on a pixel level. Future exploration of this technology would require a comparison of these results with object-based classification, alongside further and continuous ground-truthing to provide the most reliable information.

Abstract

Bruchidius terrenus (Sharp) Coleoptera: Bruchinae, is suppressor of generically potencial of introduced leguminous *Albizia julibrissin*, Durazz in significant number as a seed beetle. So far this weevil has been proven as a monophagous species in Serbia. The name of the species in the Serbian language, according usually for taxonomic affiliation and the host plant, is mentioned for the first time in our research as a Persian silk tree, or pink silk tree seed beetle. Adults were first found in 2013, in Ruma town in Autonomous Province of Vojvodina (Serbia) with the observation of insects wintering in adult stage, waiting for the silk tree flourishes from June to August. The pods are ripe from September to November. In 2014, the young adults start emergence of ripe pods (this is the latest stage of ripening) in late summer. These Bruchine can be considered as successfully adapted, and with regard to the host, i.e. with high potentional bioagent agenst host plant. The data on the percentage of infestation for the season 2013/14, varied from the dissection of pods and the maximum was 88 %. In the same period, parasitoids appear for the first time.

Key words: *parasitoids; Albizia; Bruchidius; Chalcidoidea; Serbia.*

Introduction

The genera Bruchidius (Coleoptera: Chrysomelidae: Bruchinae), which is described by Schilsky in 1905, is distributed in the old world and includes about 300 seedbeeetle species (Hoebeke at al, 2009). Bruchine are economically important as pests of agricultural storage products; for example (Ebadollahi et al., 2013; Loni & Panahi, 2015). Larvae of Bruchidius species for host plants have leguminous plants, family (Fabaceae). *Albizia julibrissin* (Fabales: Fabaceae) was introduced in Serbia, and planted as ornamental trees (Vukićević, 1996, Jovanović, 2000). During the research since 2012 in Serbia, the species *Bruchidius terrenus* (Sharp), which are parasitized by *A. julibrissin* seeds, and their parasitoids (Gagić-Serdar et al., 2012; Gagić-Serdar et al., 2013) had been recorded for the first time.

Materials and methods

The collected Populations (Figure 1) were cultivated under controlled conditions in order to obtain data on the length of each development stage. In addition to the development stages of seedbeetles, development stages of their parasitoids have also been recorded, which are further grown in plastic boxes with mesh and petri dish for the purpose of determination. The discovery of randomly selected pods revealed seed infestation according to Tuda's methodology and associates (2001). Parasitoids are determined by using interactive act keys like De Graham (1969); Trâpicéyn (1989); Medvedev (1978) & Bouček(1991) by prof.dr Ljubodrag Mihajlović.

Results and discussion

Since start of research many number of species of parasitic wasps had been determined and registered as autohtonous fauna; thez were determined as the natural enemies of granivorous *Bruchidius terrenus* (Sharp). The parasitod complex consist primary of the *Dinarmus acutus* (Hymenoptera: Chalcidoidea: Pteromalidae) and an entirely new species of Eurytomidae (Hymenoptera: Chalcidoidea). The adaptation process is still ongoing; parasitoids are indigenous species, trying even to be synchronous with development stages of Bruhinae. *D. acutus*, which is fed inside the pods, is fed in the larvae within the originally infested healthy generative material of the silk tree, and is considered to be solitary ectoparasitoid. Nevertheless, they were found by numerous species of Eulophidae (Hymenoptera: Chalcidoidea) as the base, as parasitoids of the second or third order-hyperparasitoids: Eulophid generas *Aprostocetus* and *Tetrastichus*. Nothing less important for the abundance of germination of seeds is also mentioned parasitoids that have about 15-20% of the total number of infested seeds. Information on the, biology, identity, phenology, distribution and impact of silk tree key parasitoid species in Serbia still need to be investigated in the future.

Conclusions

Parasitoids that are shown and photographed in this paper, the first time were recorded and found as *Albizia jullibrisin* weevil parasitoids and they are indigenous species that have adapted to non-native host (host plant as nonnative seed beetle). That's opens many question about their bionomy and ecology which is in a adaptive, denizen state.

Abstract

The aim of this study was to examine the response of white poplar genotypes on drought stress based on six morphometric, survival and biomass parameters. The microshoots of five genotypes (Villafranca, L-12, L-80, LBM and LCM) were cultivated on media with two different concentrations of polyethylene glycol (PEG) 6000: 20 g/L and 50 g/L, as well as on control treatment without PEG. The media were based on ACM (Aspen Culture Medium) with 9 gL^{-1} agar, 20 gL^{-1}sucrose, 1µM kinetin, 1µM benzylaminopurine (BAP) and 100 mg L^{-1} myoinositol. Results of two-way ANOVA and LSD tests suggested that the effect of media was significant for all examined traits, with clear increase in inhibitory effect by the increase in concentration of PEG. The effect of genotype was significant for number of new shoots and fresh and dry shoot mass. The effect of interaction genotype × medium was significant only for number of new shoots. The difference between genotypes was the highest on medium with the highest PEG concentration (50 g/L). This medium was suggested for further drought studies in white poplar *in vitro* including drought tolerance evaluation. The best performance was achieved with genotype L-80, and the worst with Villafranca. The study suggests significant potential of tissue culture in the research of drought tolerance in controlled conditions.

Keywords: *Populus alba, micropropagation, drought tolerance.*

Introduction

Drought is one of the principal abiotic factors that limit agricultural production. It is estimated that it globally decreases yield by 17% (Ashraf and Foolad, 2007). In wood production, the losses caused by drought are increasing. Evaluation of tolerance to abiotic factors in plants is complex process due to interactions between stress factors and physiological and biochemical processes that influence plants' growth and development (Razmjoo et al., 2008). Many researchers suggest that the basic approach to the mitigation of climate changes should be breeding and cultivation of tolerant cultivars, particularly of forest tree species tolerant to drought. In this process, the knowledge of basic mechanisms of plants' tolerance, especially of forest tree species to drought, is of crucial importance. Rubio et al., (2002) emphasize that effects typical to drought could be found as a result of influence of other abiotic factors, such as stresses caused by salt, high and low temperature. Research on tolerance of abiotic factors *in vitro* has many advantages, considering relatively fast procedures methodology, high number of repetitions in controlled conditions, etc. (Cui et al., 2010; Kovačević et al., 2013a; Kovačević et al., 2013b, Vuksanović, et al., 2019).

In spite of its high adaptability, white poplar is considered endangered species in Serbia, which gives special importance to its use in preservation and improvement of biodiversity in general (Kovačević et al., 2010a). Beside the establishment of plantations dedicated to wood production (Rédei et al., 2013), this species is used in horticulture and landscape architecture as well, especially genotypes with pyramidal crown form (Kovačević et al., 2010b). White

poplar has important role in biotechnological research, where it is considered as model tree species (Confalonieri et al., 2000). Generally, poplars are good candidates for such research considering the fact that the genome of *Populus trichocarpa* has been completely sequenced (Tuskan et al., 2006).
The main aim of this study was to evaluate *in vitro* tolerance of white poplar genotypes to PEG-6000 induced drought conditions, in order to find tolerant genotype which could be used in horticulture, landscape architecture and wood production.

Material and methods

Five genotypes of white poplar (*Populus alba* L.) were used in this study: experimental Serbian genotypes: L-80, L-12, LCM and LBM and well-known Italian genotype *cl.* Villafranca, regarded as control genotype. Examined group of genotypes genotypes are characterized by vigorous growth in tissue culture and genetic diversity (Guzina and Tomović, 1989; Kovačević et al., 2013b). Shoots 10-15 mm high were cultivated 35 days on modified Aspen Culture Medium (Ahuja, 1984) for multiplication with added 9 g/L agar, 20 g/L sucrose, 1μM kinetin, 1μM BAP and 100 mg myo-inositol. Effect of two concentrations of polyethylene glycol (PEG) 6000: 20 g/L and 50 g/L added in multiplication medium were examined, while medium with no PEG was used as Control. Sterilization was performed by autoclaving. Cultures were cultivated in jars 120 mL in volume, with 25 mL on medium in each, on temperature t = 26 ± 2°C, white light provided by LED lamps with 3500 lx/m^2 in 16h/8h day/night regime. After 35 days of *in vitro* cultivation following parameters were measured: length of the longest shoot, number of new shoots, survival rate, multiplication rate, fresh and dry shoot mass.

Statistical analysis

The significance of the influence of examined sources of variation and differences between treatments were tested by two-way ANOVA and Fisher's LSD test at the level of α=0.05. All statistical procedures were performed by Statistica for Windows version 13 (TIBCO Software Inc., 2017).

Results and discussion

After testing of applied PEG concentrations, results of analysis of variance showed significant effect of media on all examined parameters. Effect of genotypes was statistically significant for number of new shoots, fresh and dry mass, while effect of interaction genotype × medium was significant only for number of new shoots (Table 1.).
Drought caused by polyethylene glycol had significant inhibitory effect on all examined parameters. According to the totals for genotypes, best general performance achieved genotype L-80, especially according to the results for fresh and dry shoot mass. (Table 2.).The poorest results had genotypes LCM and Villafranca. Generally, plants on medium with 50 g/L PEG achieved 20% lower shoot height, 37% less new shoots, 30% lower multiplication rate and 33% less fresh shoot mass comparing to the Control.
Results of LSD-test confirmed significant effect of tested PEG concentrations on examined morphological and biomass parameters (Table 3.). The shoot height on the highest examined concentration of PEG (50 g/L) varied from 10.6 mm (L-12) to 14.13 mm (LCM). The highest survival rate on 50 g/L PEG achieved L-80, and the lowest L-12. The lowest multiplication rate achieved Villafranca. The highest fresh and dry shoot mass per jar on medium with 50 g/L PEG achieved L-80. No significant differences between genotypes on this medium were found for number of new shoots.

a) The differences among values of particular characteristic marked with the same letter are not significant at the level of α0.05.

Results of analysis of variance and LSD-test for examined parameters suggest decrease of shoot height with the increment of PEG-6000 concentration in medium in all examined genotypes, which is in concordance with recent studies (Lei et al., 2006; Yin et al., 2005; Yang and Miao, 2010). Achieved results also present difference between examined genotypes in their response to the drought caused by PEG, with the strongest inhibitory effect of 50 g/L PEG concentration. Also, the most evident differences between examined genotypes have been found on 50 g/L PEG-a, which purposed this medium for further drought tolerance research.

The smallest decrement of shoot height on medium with 50 g/L PEG was found for genotype L-80. Also, this genotype achieved 100% survival on the driest examined medium. The strongest inhibitory effect on biomass parameters of this medium was found in genotype Villafranca, and the weakest for L-80. Studies on drought tolerance *in vitro* was performed also by Abdulmalik et al., (2018). They examined drought tolerance of peanut cultivars on modified MS media with different PEG-6000 concentrations (0, 20, 40 and 60 g/L). They

found decrement of examined morphometric parameters (shoot height, root length, number of shoot and roots per plant) with the increment of PEG-6000 concentration.
After study of drought tolerance on media with 20, 40 and 60 g/L PEG after one month long cultivation *in vitro*, Manoj and Uday, (2007) observed that root length, shoot height, as well as shoot and root mass decreased with increment of PEG concentration in medium, with stronger effect of drought on root length then on shoot height.

Table 3. LSD test for examined parameters at the level of interaction genotype × medium.

**) The differences among values of particular characteristic marked with the same letter are not significant at the level of α=0.05*

Conclusions

According to the results of our study, genotype L-80 achieved good shoot growth, high survival rate, high fresh and dry mass accumulation, and in all these parameters it exceeded Villafranca, that was considered as standard genotype in this study. That is why L-80 could be suggested as the most tolerant genotype within examined group of genotypes for cultivation on habitats burdened with drought. Results of *in vitro* tests in this work suggest that the examined parameters could be indicative for the selection of white poplar genotypes for drought tolerance. Thus, further research of drought tolerance should be directed to examination of larger group of genotypes and species by implementation of same or similar methodology.

Acknowledgments

This paper was realized as a part of the projects „Studying climate change and its influence on the environment: impacts, adaptation and mitigation" (43007) financed by the Ministry of Education and Science of the Republic of Serbia.

Abstract

Identifying the component and distribution of some important species of mangrove forest in Kien Giang and Ca Mau will be useful for the strategy of mangrove forest protection development. After a preliminary survey of the entire forest, random measurements of 3 plots were used to calculate the coefficient of variation as a basis for calculating the sample size needed to conduct forest surveys. The area is required for the study is 1,666 ha, with a 95% confidence level and 10% error, each plot needs 100m^2. The results of survey show that natural forests and coastal forests (apart from shrimp farms) are the main protective forest belt of the coastal line, so there are only 17 species belonging to 11 families of plants including 14 species woody plants, three shrub species, in which the *Rhizophora* (*Rhizophora apiculata*-Duoc) and *Avicennia* (*Avicennia* sp. -Mam) families are dominate. Regions can be grouped into four sub-regions depending on number of species as well as component of each species. At the similarity level of 40% of the plots, it can be divided into 5 groups. The analysis results show as follows: Group 1 has dominant species like Euphorbiaceae (*Excoecaria agallocha*-Gia), Group 2 dominant species is White *Avicennia* (*Avicennia alba* -Mam trang), Group 3 has 4 dominant species: White *Avocado*, *Avicennia*, *Sonneratia* (*Sonneratia* sp.), *Rhizophora*. Group 5 has 2 dominant species as Black *Avicennia* (*Avicennia officinalis*- Mam den) and *Rhizophora* (*Rhizophora apiculata*-Duoc). In conclusions, Mangroves and Black *Avicennia*, it should be considered for developing and protecting mangrove forest.

Keywords: *Avicennia (Mam), Some imforttant species, Mangrove forest, Myrsinaceae (Su), Rhizophoraceae (Vet, Duoc),*

Introduction

Western mangroves in the Mekong Delta, mostly located in Kien Giang province and part of Ca Mau province borders An Minh district of Kien Giang; from An Minh to Ca Mau due to erosion of the sea, the area of natural forest in this area is severely damaged, so the area of natural mangrove forest is mostly in Kien Giang province. Vietnam has 3,260 km from Mong Cai, Quang Ninh province to Dat Mui, Ca Mau province. With a long coastline, many regions and regions have different natural conditions, so the distribution of mangrove species is also different. Particularly, mangrove forests in the west of Kien Giang and Ca Mau have more than 308 km from the Cambodian border to the boundary of Ca Mau Cape. Mangroves are typical ecosystem in the estuary of tropical and subtropical coastal areas, with rich and diverse biological resources, which are the boundary between land and sea, so it plays a particularly important role in the protection of sea dykes, fixed sediment encroachment on the sea, limiting the harms of storms, protecting accretion, preventing coastal erosion, limiting saltwater intrusion, protecting ecological environment.

The Western Sea region of Kien Giang province including An Minh, An Bien and Rach Gia city, Hon Dat, Kien Luong and Ha Tien town have more than 208 km of coastline, of which about 170 km of mangrove forest distribution with a total area of forests and coastal protective forest land of 8,365 ha (Kien Giang Department of Agriculture and Rural Development, 2012). In recent years, due to various reasons, the area of mangrove forests has been seriously destroyed, affecting production and people's lives in coastal areas. According to data from the Ministry of Agriculture and Rural Development, the area of mangrove forests in the whole country in 1943 was 408,500 hectares, until 1982 only 252,000 hectares (General Department of Forestry, 2010).

The surface water environment of the coastal area is affected by many factors such as extensive and intensive shrimp farming areas, residential areas and aquatic processing facilities along the region. The rule of delta formation is due to the accumulation of accreted sediments, the mudflats gradually rise and rise, at low tide the ground is exposed. These are conditions for suitable species to spread seeds to grow, then stabilize and develop into a forest related to a group of Mam species (*Avicennia* sp). When the population of Avicennia forest has formed and the mudflats are stable, other species such as Su and Vet ... will follow to continue strengthening soil, until the mud soil has stabilized. For those reasons, the topic: "Identification of the component and distribution of some important species of mangrove forest in Kien Giang and Ca Mau" was carried out to determine the composition and distribution of some important species of mangrove forests in Kien Giang and Ca Mau provinces, from that strategy for protecting mangrove forest will be done in future.

Material and Methods

Descriptives of Research place

Kien Giang and Ca Mau are two provinces in the Mekong delta, located from 101^0 30' to 105^0 32' Eastern Longitude and from 9^0 23' to 10^0 32' Northern Latitude. This area is shown in Figure 1.

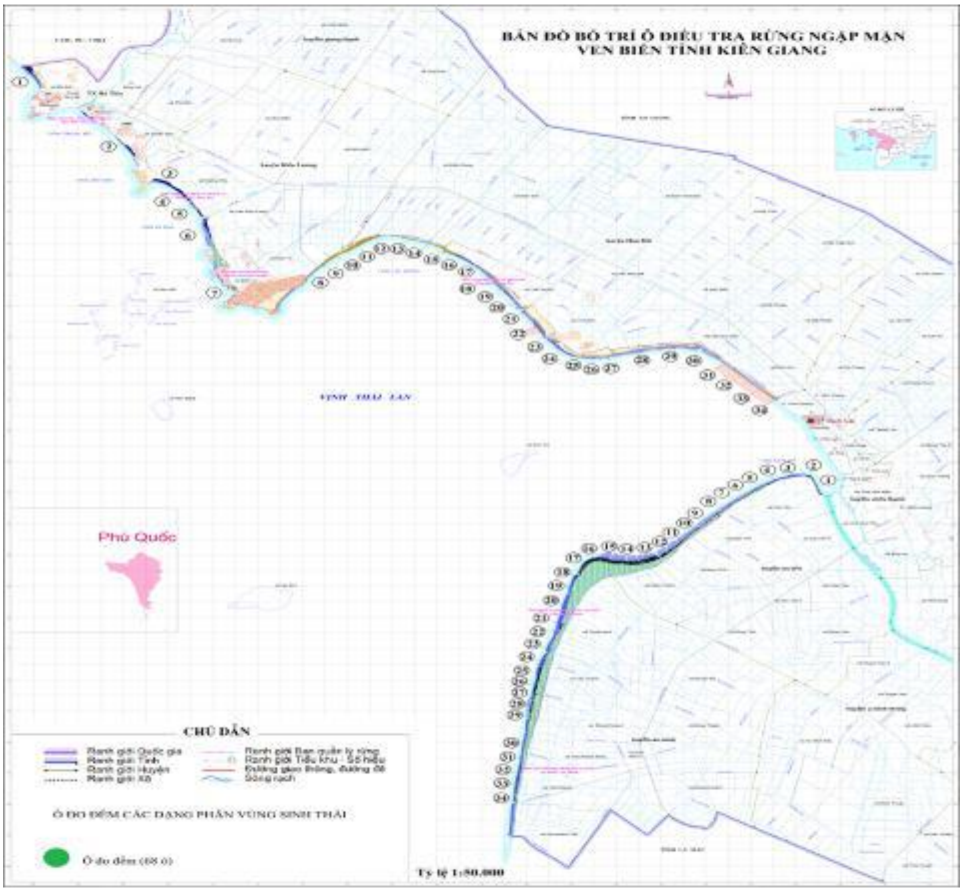

Figure 1. Map of plot arrangement measuring mangrove forest in the study area.

Survey methods

- After a preliminary survey of the entire forest, random measurements of 3 plots were used to calculate the coefficient of variation.
- Depending on the purpose of the investigation, the accuracy is controlled differently. In the given agro-forestry research, the reliability is usually equal to 95% and 10% of the given error. The number of sample plots required for investigation ensures reliability is calculated according to the formula (Nguyen Ngoc Binh, 2006):

$$n = \frac{4N(S\%)^2}{N(\Delta\%)^2 + 4a(S\%)^2}$$

where: n: Number of plots N: Total capacity (N=f/a)

a: Area of sample plot F: Area of survey region

Δ%: Preset Error (10%)

S%: Coefficient of Variation; S% = S/ $\overline{x}$*100

where: S: Sample Standard Error

$\overline{x}$: Sample average

Applying the above method to calculate the number of sample plots to be investigated, it is necessary to first investigate 3 sample plots to calculate the coefficient of variation on trunk diameter at 1.3 m (D1,3) of sample plots. Area of each plot is 10m x 10m = 100m^2 due to typical determination, so the distance determined based on the forest distribution surveyed and the previous coordinates determined, determine the relevant values to calculate, the results are as follows:

Average = 6,73787 Stdev = 4,787777

S = 0,2108 S% = 21,08%

$$N = \frac{F}{a} = \frac{\textit{Area of survey region}}{\textit{Sample plot Area}} = \frac{1.666ha}{100m2} = \frac{16.660.000m2}{100m2} = 166.600$$

$$N = \frac{4N(S\%)^2}{N(\Delta)(\Delta\%)^2 + 4a(S\%)^2} = \frac{4*166600*444.37}{166600*100+4*100*444.37} = 8,8$$

Based on the West Sea mangrove current status map of Kien Giang and Ca Mau provinces, survey lines were arranged from the mainland to the sea so that the plot was located at the center of the forest belt. The points and survey plots were defined in advance coordinates on the digital map as a basis for determining the field location. The total number of plots was 68 plots on 2 routes, each of which has 34 plots shown in Figure 1.

- Characters for measuring: Determining tree species, trunk diameter at breast height (D1,3), peak height (Hvn), average diameter of tree canopy (Dt) perpendicular 2 toward the East-West and South-North, deduce the canopy section (Gt) by the formula:

$$Gt = (\frac{D}{2})^2 \times \pi$$

Growth level: Quality classification of standing trees (He) is the growth level of trees according to a scale of 5 (1 point is dead tree; 2 top tops; 3 normal growth plants; 4 good growth trees of copper 5 plants with strong growth, outstanding height, straight body, high branches).

Data analysis methods

Microsoft Excel 2013 was used to analyse data and graph. PRIMER 6 software was used to analyse species similarities: Variables where standardized by Square root method, then set the same matrix according to Bray-Curtis method and draw branch diagrams by group average (Group average) to consider at similar levels. SPSS version 10.0 software was used to process data, using the ANOVA method and Duncan test at the 5% significance level to compare the differences among the study areas.

Results and Discussion

Components of plant species

The results of the mangrove forest survey show that natural forests and coastal forests (apart from shrimp farms) are the main protective forest belt of the coastal line, so there are only 17 species belonging to 11 families of plants including 14 species of woody plants, three species of shrubs, in which the Rhizophora (Duoc) and Avicennia (Mam) families are dominate. Details of plants and species of mangrove forest are shown in Table 1.

Table 1. Plant species component of mangrove forest in Kien Giang province.

No.	Families	Scientific name	Local name
1	Myrsinaceae	*Aegiceras corniculatum*	Su
2	Avicenniaceae	*Avicennia alba*	Mam trang
3	Avicenniaceae	*Avicennia marina*	Mam bien
4	Avicenniaceae	*Avicennia officinalis*	Mam den
5	Rhizophoraceae	*Bruguiera cylindrical*	Vet tru

17	Malvaceae	*Hibiscus tiliaceus*	Tra

Research area depending on ecological conditions can be divided in four sub-regions that are shown in Figure 2.

Growth characteristics of mangrove species in sub-region 1

In sub-region 1, there are 7 species with density of 6,100 trees/ha. Species with number of dominant trees are Black Avicennia, accounting for 45%; The dominant species in the high tier is Ban oi, which accounts for a low proportion in the community of 11.75%; *Rhizophora* is the species with the second high ratio with the density of 32.5%; *Avicennia* (Mam trang) has a low ratio of 4.9%; Vet du, though accounting for a low rate of 3%; Gia is only 1.9%.

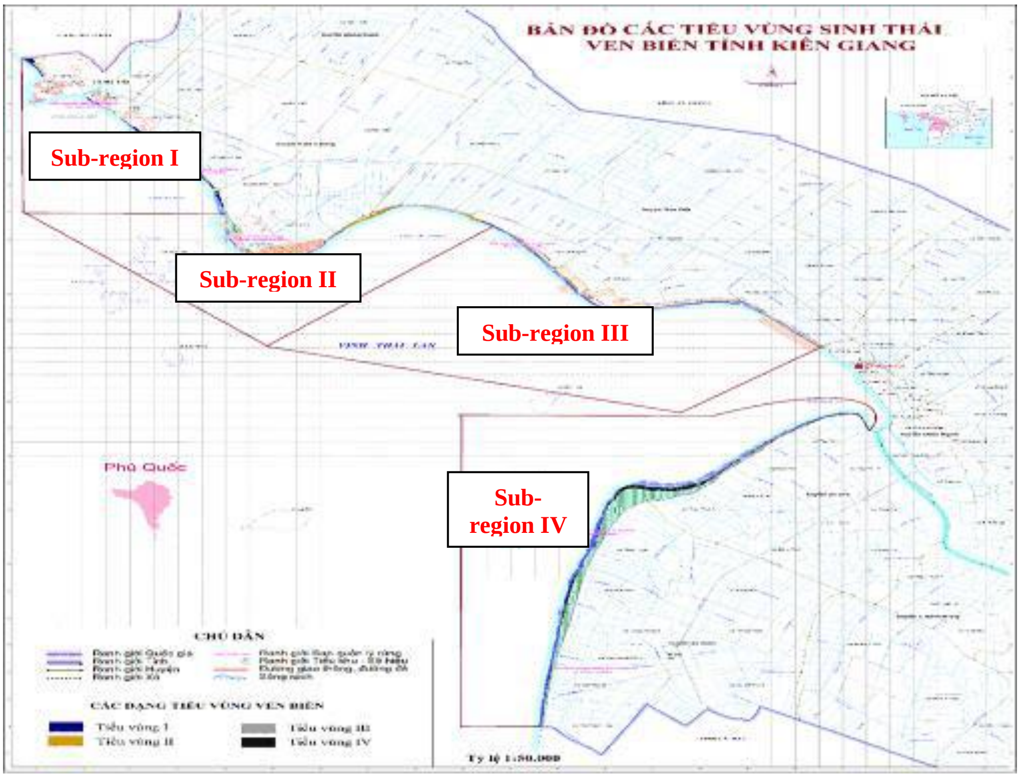

Figure 2. Four sub-regions represent for different ecological conditions in study area.

Growth characteristics of mangrove species in sub-region 2

Sub-region 2 has 12 species, expressing biodiversity here. It is higher than other sub-regions; for example, species composition is high, an endemic species is known as Coc do species. This species is being conservation of genetic resources. Besides, the density of forest trees here is quite high, 4,100 trees/ha; regarding density structure, the density of black Avicennia is 1,190 trees/ha, accounting for 29%; the second species has high density is White Avicennia 20%, the third highest density is Gia about 18%. Species have the fourth highest density is Rhizophora with 13%, other species account for less than 1% to 6% including Coc do, Coc trang, Su, Vet du, Ban chua, Tra, Binh bat, Ngoc Nu.

Growth characteristics of mangrove species in sub-region 3

In the ecological sub-region 3, there are 8 species: the dominant species with the highest density are Mam trang with 32%, the species with average appearance rate of 13-21% having 3 species of Rhizophora, Mam bien, Nypa palm; and species with low percentage smaller than 7% such as Gia, Vet du, Ban chua and Dung.

Growth characteristics of mangrove species in sub-region 4

In sub-region 4, there are 10 species and an average density with 2,450 trees/ha. This is the form of forest with many mixed species with 10 species surveyed: species with dominant density are Black Avicennia with 49% in all sub-regions, other species with high density such as White Avicennia accounts for 27%, Rhizophora accounts for 15%, other species such as Gia account for nearly 6%, the rest are accounted for below 1% like Ban oi, Ban chua (Sonneratia), Vet du, Coc trang, Avicennia, Vet tru.

The relationship among communities

There is not significant at similarity relationship of 20%. At the similaity level of 40% of the plots, it can be divided into 5 groups. In each community group or main forest structure type, each forest type has different dominant species.

- Group 1 has dominant species like Gia, and there are 3 types of structure with total of 3 cells, accounting for 4.41%.
- Group 2 dominant species is White Avicennia, and there are 5 types of structure with total number of cells is 14 accounting for 20.58%.
- Group 3 has 4 dominant species: White Avocado, Avicennia, Sonneratia, Rhizophora. Of which, White Avicennia has 7 types of structure with a total of 7 cells occupy 10.29%. The Avicennia species has 4 types of structures with a total of 4 plots make up 5.88%. There are 2 species of Sonneratia and Rhizophora, each species has 1 type of vicwstructure and only 1 cell, accounting for 1.47%.
- Group 4 has 2 dominant species: Rhizophora and White Avicennia. In particular, Rhizophora is the main dominant species, and there are 9 types of structures with 9 cells account for 13.23%. The rest are White Avicennia species with 1 structure type and only 1 cell accounting for 1.47%.
- Group 5 has 2 dominant species as Black Avicennia and Rhizophora. In particular, Black Avicennia is the main dominant species accounting for 22 cells/28 cells. There are 11 types of structures, total of 22 cells accounting for 32.35%. The dominant species is Rhizophora with 6 types of structure, a total of 6 plots account for 8.82% of the measured plots.

Conclusions

The composition and distribution of some species in the West Sea mangrove forest have 17 species of 11 plant families including 14 species of woody plants, 3 species of shrub species. About the relationship between species in the study area at the same level of 40% of plants divided into 5 main groups with 47 community types, 6 dominant species, including Mam đen [*Avicennia officinalis*], Mam trang [*Avicennia alba*], Duoc [*Rhizophora apiculata*], Gia [*Excoecaria agallocha*], Ban oi [*Someratia caseolaris*]. Vet du [*Bruguiera yipamoriza*]. The distribution of species showed that Mam den [*Avicennia officinalis*] has the highest rate, the second species is Duoc [*Rhizophora apiculata*], and the third species is Mam trang [*Avicennia alba*]. It should be proposed in the afforestation on new land warped in the study area.

Sub-region 1, the composition of mudflats has a ratio of clay composition of 12.53%, flesh soil composition of 19.45%, sand of 68.02%. Due to the site conditions, this sub-region has very high sand content of 68%. No new forest planting should be conducted, but natural regeneration should only be conducted so that seedlings can adapt themselves to places where there are favourable conditions.

Sub-region 2 has natural conditions with the ratio of 4.19% organic, 54.71% clay, 36.10% meat, 9.19% sand, total salt in soil 6.33 ‰, soil pH 8,11, and EC = 9,89mS/cm. This sub-region has a favorable condition of natural fertility, with a sufficient amount of sand, a high content of flesh soil, and a high percentage of organic ingredients, thus it only increaseas the composition of plant humus into the potting medium with a rate of 5-10% enough.

Sub-region 3 has ratio of 7.29% soil organic matter, 52.29% clay, 45.89% flesh soil, 1.82% sand, total salt dissolved in 6.44‰ soil, pH 6.89, and EC = 10,06 mS/cm. As this sub-region has high clay and flesh soil content, low sand ratio, high organic composition, it is suitable for plantation and afforestation.

Sub-region 4, there are ratio of soil organic matter 2.34%, clay 55.59%, flesh soil 43.84%, sand 0.57%, total soluble salt 8.83 tan, soil pH 7.54, and EC = 13.8 mS/cm. This is a place with a fairly large mudflat, high clay and flesh sol content, low organic matter content in the soil, so it only pays attention to increase the ratio of organic matter in the potting mix from 5 - 10% to increase porosity and humus content for seedlings.

CHARACTERISTICS OF ALKALIZED SOILS IN THE BAČKA REGION (SERBIA) AND THE POSSIBILITY OF THEIR AFFORESTATION

Saša PEKEČ[1*], Marina KATANIĆ, Vladislava GALOVIĆ, Velisav KARAKLIĆ

University of Novi Sad, Institute of Lowland Forestry and Environment, Novi Sad, Serbia

Abstract

Alkalized soils occupy 80,333 ha or 3.75% of the total area of Vojvodina and represent the areas fragmentally covered with scarce halophytic shrubby vegetation. Besides alkalization processes endanger about 34,000 ha, or 1.60% of primary agricultural land, which represents in total 5.35% areas endangered with alkalization in Vojvodina. Bearing in mind the surfaces that are endangered by alkalization, in the Bačka region, the study of alkalized soils was carried out on relief forms in the form of depressions representing river basins from the geological past. In these relief areas of Bačka, where alkalisation is present, alkalized soil is formed at the soil type designated as solonetz, class solonci. The paper presents the properties of solonetz soils, ie their physical and chemical properties. The study of these soils is significant for the purpose of finding a suitable method for the melioration of such areas. On the basis of the soil studies, the tree species that can be planted on these habitats will be determined. The soil quality of these areas will be improved through forest establishment.

Keywords: *Alkalized soils, Afforestation, Forest melioration*

Introduction

Alkalised soils occupy mostly lower relief positions and appear in spots, on sedimentary substrates, loess, loam and clay. Their formation is accompanied by a series of complex processes, and the basic process is sodium embedding in the adsorptive complex and its relatively high presence. In the area of Vojvodina, these lands are mostly widespread in Banat, somewhat less in Bačka and the least in Srem. According to Ivanišević et al. (2011) alkalisation, as a degradation process, endangers also the peripheral parts of agricultural soils. According to Miljković, (2005) solonetz is most oftenly located in the complex with solonchak and other saline soils of automorphic and hydromorphic origin, which are affected by processes of alkalization, salinization and desalination. The usage of the production potential of these soils requires different meliorative operations, and the solonetzes, due to their unfavorable chemical and physical properties, are used as natural, rather scarce pastures. According to the benefits for plant production, these lands belong to the seventh grade (Hadžić, et al. 2002). Given the unfavorable conditions for the use of these soils, Ivanišević et al. (2013) propose the establishing of tree plantations to prevent the process of further salinisation of these soils, so tree plantations would have a semimelioration function. According to Roncevic (2014), as stated by Kadovic, (1983); Galić, (2006) and Ivanišević et al. (2013), it is important to choose woody species that are tolerant to these unfavorable soil conditions and which can contribute to mitigation of further degradation processes. The aim of this research was to show the characteristics of alkalized soils and the possibility of their afforestation with certain types of trees.

Material and methods

In this paper, alkalized soils in the region of Bačka (Serbia) were studied. Soil surveys were carried out in the fields of the towns Futog-Begeč and Kovilj. Pedological profiles were opened and their external and internal morphology were described. Soil samples were taken in deteriorated state, and physical and chemical analyzes of samples were made in the

laboratory. The following analyzes were performed:
Determination of granulometric composition of soil according to international B-pipette method by preparation in sodium pyrophosphate (Bošnjak et al. 1997)
Determination of mechanical elements was made by Atteberg, and the texture classes were determined according to the American classification (Belić et al. 2014)
Determination of humus content in soil by the Tjurina method by Simakov modification, 1957
Determination of the content of CaCO3 in the soil, volumetric with the Scheibler calcimeter,
Determination of chemical reaction of soil, pH in water electrometric with glass electrode,
Determination of the content of total water soluble salts in soil by the method of measuring electrical conductivity in the saturated soil trap.

Picture 1 Location of pedological profiles

Results and discussion

Analyzing the granulometric composition of the studied soils (Table 1), it can be seen a very small fraction of coarse sand, on average only 0.8 to 1.8%, and an increase in the fine sand fraction ranging from 36.0 to 56.3% , as well as the share of silt whose values are from 26.6 to 37.3%, while average share of colloidal clay was slightly lower, or from 15.2 to 26.6%. According to the total content of sand and clay, we can conclude that the average content of total sand is in the range of 36.9 to 58.1%, while the average content of total clay is from 41.8 to 63.1. According to Ćirić, (2012) this soil has a heavier mechanical composition with more than 30% of clay. Characteristics of alkalized soils have been investigated in detail in the works of Belić et al. (2004) and Belić (2005).

Table 1 Granulometric composition

P2 *Rončević et al. (2014)

It is particularly evident that in iluvial $Bt,_{na}$ the horizon of these soils the content of total clay was increased. This horizon with its morphological, physical and chemical characteristics is the basic diagnostic horizon of this type of soil. The textural classes of this iluvial horizon are: clay loam and clay, while the remaining horizons of these lands are: loamy sand, sandy clay and clay.

Table 2 Chemical properties

P2 *Rončević et al. (2014)

Analyzing the chemical properties of this soil (Table 2), it is estimated that the average pH value for these soils was from 8.24 to 9.05, and the tested soils are medium to very alkaline. Observing the humus content, it is evident that the highest humus content is in surface horizons, and the humus content decreases with the depth of the profile. The average values of the humus content are in the range from 0.38% to 4.63% and classify this land in very poorly humid to quite humid. The carbonate content grows slightly with depth of soil, except in the lowest Gr or R horizons. The average values of carbonates are 15.58% and 16.95% respectively, and according to the classification, these lands are classified into highly carbonate soils. The total salt content varies in these soils and is highest in the eluvial $Bt,_{na}$ the horizons with values of 0.25%, 0.30% and 0.12%. It is also noticeable that the increased salt content in the horizons below $Bt,_{na}$ the horizon, or in C_{ca} horizons in the P2 and P3 profiles, with values of 0.16% and 0.14% indicating the occurrence of increased sedimentation in these horizons for the tested soil. Since soils in degradation have heavier mechanical composition and the alkalization process (Pekeč, 2016), it can be concluded that the ecological and production value of these soils depends largely on the content of the total water-soluble salts and the mechanical composition of the soil.

The analyzed alkalized soils are solonetz type, morphological structure AE-$Bt,_{na}$-C_{ca}-Gr (R) or A_{oh}-$Bt,_{na}$-C_{ca}-R. Texture migration, due to eluvial-illuvial processes from surface horizons in the illuvial horizon, is present in these soils. The horizon of the determination of these soils is iluvial Bt, na a horizon at a depth of 20-50cm, 15-60cm and 35-65cm, which is characterized by a high proportion of total clay from 56.8 to 73.8%. It is very compact and also

distinguished with high content of total salts (0.12-0.30%) and high pH values. The power of this horizon is 30-45cm with stubble structure and unfavorable water-air features.
High content of sodium and heavy mechanical composition in Bt_{na} horizon are the cause of the lack of favorable water, air and heat regime of this horizon (Hadžić et al., 1991)
Given these poor physical and chemical characteristics, there are no woody species on these soils and mainly pastures are present. Large areas with this kind of soils are under halophytic vegetation, without woody species, with sparsely arranged bushy formations of *Cornus mas*, *Prunus spinosa* and *Pyrus pyraster*. Studying the reception of various species of trees at the solonetz, Rončević et al. (2014) highlighted the particularly good reception of narrow-leaved ash (*Fraxinus angustifolia*), domestic white poplar (*Populus alba*), Russian olive (*Eleagnus angustifolia*), white mulbery (*Morus alba*) and Turkey oak (*Quercus cerris*).
It is important to emphasize that such soils could be afforested only with species with high increase. According to Pekeč et al. (2010), bearing in mind the characteristics of these soils, wood species for their afforestation should be tree species that can endure such unfavourable habitat conditions, primarily the following types of trees: wild pear (*Pirus piraster*), Russian olive (*Eleagnus angustifolia*), various species of the genus *Prunus sp*., white poplar (*Populus alba*), pedunculate oak (*Quercus robur*), Turkey oak (*Quercus cerris*) and narrow-leaved ash (*Fraxinus angustifolia*). It can certainly be said that such soils can be afforested only by a narrow spectrum of forest trees which are resistant to such unfavorable edaphic conditions.

Conclusion

In the Bačka region, individual parts are exposed to degradation processes of alkalization, which occupy generally lower relief positions. The use of the production potential of these soils requires different meliorative operations, and the solonetzes are used as natural pastures due to unfavorable chemical and physical properties. The analyzed alkalized soils are of solonci class, solonetz type, morphological material AE-$Bt,_{na}$-C_{ca}-Gr or Aoh-$Bt,_{na}$-C_{ca}-R. Texture migration due to eluvial-illuvial processes is present in these soils from surface horizons to the horizon of illuviation. The horizon for the determination of these soils is illuvial Bt, na the horizon which is at the depth of 15-65 cm in the studied soil, with power of 30-45 cm. It is characterized by a high proportion of total clay, increased alkalinity and increased content of total salts, which is a limiting factor for plant production. The soils with such unfavorable properties can be afforested with a narrow spectrum of forest trees which are resistant to these unfavorable edaphic conditions. The afforestation would partially improve the properties of these soils through forest meliorations.

Aknowledgement

This paper was realized as a part of the project "Studying climate change and its influence on the environment: impacts, adaptation and mitigation" (III43007) financed by the Ministry of Education and Science of the Republic of Serbia within the framework of integrated and interdisciplinary research.

THE EFFECTS OF CLIMATE CHARACTERISTICS ON THE DIAMETER INCREMENT OF DOUGLAS-FIR IN THE CITY OF BELGRADE (SERBIA)

Tatjana RATKNIC*, Mihailo RATKNIC, Zoran PODUSKA, Ivana ZIVANOVIC, Nemanja LAZAREVIC, Sabahudin HADROVIC

Institute of Forestry, Belgrade, Serbia
*Corresponding author: tatjanaratknic@yahoo.com

Abstract

The paper presents the results of a study dealing with the effects of climate factors on the size of the early and late wood as well as the total diameter increment of Douglas-fir. For the purpose of this analysis, 30 increment bores were taken at breast height. The research was conducted in the area of Belgrade (Serbia) on the site of European Turkey oak and Hungarian oak (*Quercetum farnetto-cerris aculeatetosum*). The obtained data were related to the mean-monthly air temperatures (in the period from April to October) and the monthly rainfall totals (in the period from April to September). The research included another very important parameter - the age of trees. The amount of rainfall in April, as well as the air temperatures in May, August and September, had a negative effect on the total diameter increment. The share of latewood was negatively affected by the amount of rainfall in April and September, as well as by the air temperatures in June, August and September. The share of earlywood was negatively affected by the amount of rainfall in April and May, as well as the temperatures in May. The analyzed parameters explained 54.2% of the current diameter increment, 33.9% of the share of latewood and 51.1% of the share of earlywood. In order to meet future requirements of forest management, growth models sensitive to climate characteristics and adaptability of Douglas-fir to changing environmental conditions have been developed.

Keywords: *adaptability, climate change, Douglas-fir, earlywood, latewood.*

Introduction

Apart from extending the growing season and increasing the storage of CO_2 and nitrogen, climate change contributes to the rapid growth of forest trees. Forest growth in changing climate conditions cannot be accurately predicted without studying the impact of climate factors on trees. A great number of studies indicate that the accumulation of gases causes the greenhouse effect (IPCC 2001). In the past 200 years, new species have been introduced from different parts of the world into European forests. Since they occupy a significant area today, the need for forest management practices in a changing environment has arisen. Dendroclimatological research can be used to identify the major climate condition factors that affect the radial growth of trees (Lopatin et al, 2008; Wager and Baker, 2003.

Douglas-fir was introduced to Europe as a decorative tree for arboretums and parks in 1827. Since the end of the 19th century, it has been planted in the forests of many European countries, especially after World War II (Vrcelj-Kitic, 1982). Today, Douglas-fir is the most commonly used allochthonous tree species in European forests and its forests cover more than 800,000 ha. Table 1 shows the general characteristics of natural habitats and the sites of the study stand in the area of Belgrade.

Table 1. Climate data for five subdivisions of the range of Douglas-fir

Climate data	Pacific Northwest		Rocky mountains			Belgrade (Serbia)*
	Coastal	Mountainous	Northern	Central	Southern	
Temperature (^{0}C)						
July	20-27	22-30	14-20	14-21	7-11	19.8 to 27.0
January	-2.5 to 2.5	-9.0 to -2.5	-7.0 to -2.5	-9.0 to -6.0	0 to 2.0	-2.0 to 7.6

Source: Valeriu – Norocel, 2019, *Ratknic, 2019.

The aim of this study was to determine the impact of climate characteristics on the diameter increment and the share of earlywood and latewood.

Material and methods

The research was carried out in an artificially-established Douglas-fir stand in Suplja Stena area near Belgrade (Serbia). The studied stand was planted in 1961 on the site of European Turkey oak and Hungarian oak (*Quercetum farnetto-cerris aculeatetosum*). The data were collected during 2018. It is at an altitude of 276 meters with a slope of 50º and a western aspect. The stand is complete and well-preserved. The bedrock underlying the stand is made of serpentine. The total number of trees is 208 per ha. Most trees range from 37.5 cm to 42.8 cm in diameter. The mean height of the stand is 43.35 cm, and the mean diameter is 43.1 cm. It has a tree distribution line typical of even-aged stands. The volume distribution line is also typical – characteristic of even-aged stands. The total basal area is 30.7 m^2ha-1, while the total wood volume amounts to 275.97 m^3ha-1. The distribution of wood volume by diameter classes is the result of the distribution of the tree number. The maximum is in the diameter class of 52.5 cm. The general data on the artificially-established stand are shown in Table 2.

Results and discussion

The dependence of the current diameter increment and width of earlywood and latewood on climate characteristics (precipitation by months and monthly air temperature averages during the growing season – from April to September) was investigated. Independent variables were precipitation sum in April (AP_P), precipitation sum in May (MA_P), precipitation in June (JU_P), precipitation in July (JL_P), precipitation sum in August (AV_P), precipitation sum in September (SE_P), mean air temperature in April (AP_T), mean air temperature in May (MA_T), mean air temperature in June (JU_T), mean air temperature in July (JL_T), mean air temperature in August (AV_T), mean air temperature in September (SE_T). A linear regression model of the impact of the age and the analyzed climate factors on the current diameter increment (Zi), share of latewood (Ka) and share of earlywood (Ra) was constructed. The model parameters are given in Table 3.

The amount of rainfall in April, as well as the air temperatures in May, August and September, had a negative effect on the total diameter increment. The share of latewood was negatively affected by the amount of rainfall in April and September, as well as by the air temperatures in June, August and September. The share of earlywood was negatively affected by the amount of rainfall in April and May, as well as the temperatures in May.

Table 2. General data on the artificially-established Douglas-fir stand

Diameter class (cm)	N		H_{mean}	G		V (m^3)	
	1 ha	%	(m)	(m^2/ha)	%	1 ha	%

Principal Component Analysis (PCA) was applied to determine the variability of data between and within the analyzed climate characteristics in order to select the best variables for discrimination. The results of these analyses are presented numerically and graphically.

Five components were isolated in the principal component analysis (PCA) (Graph 1). The results of this analysis are shown in Table 4. According to the eigenvalues and percentage values obtained, the first five components (coordinates) are sufficient to explain 73.716% of the total variability of data. The value each variable (climate factor) contributes to the overall variability of data (according to the first, second and third axes) is shown in Table 5. The scatter plot (Graph 2) shows the geometric distance between the studied climate parameters and the variability between them.

Graph 1. Number of identified components and their eigenvalue

Based on the transient diagram shown in Graf 2, it can be seen that of the 13 tested factors, two components best explain the variability in the sample. The correlation between the mean air temperature in August (AV_T), year, mean air temperature in July, mean air temperature in June (JU_T), and mean air temperature in April (AP_T) determines the basic characteristics of component 1. The connection between the precipitation sum in May (MA_P), precipitation in July (JL_P), and precipitation in June (JU_P) defines component 2.

Conclusions

A clear long-term trend of changing climate has been identified. It can be concluded that the analyzed parameters explain 54.2% of the current diameter increment, 33.9% of the share of latewood and 51.1% of the share of earlywood. For forest management purposes, new growth models that are sensitive to climate characteristics and their changes in forest ecosystems need to be developed.

Abstract

In our forests, around 2.94 mil. m^3 of dendromass is cut down each year. Of these, about 4-6% or 117,000 to 176,000 m^3 makes wood greenery - twigs with needles or leaves, with 10 mm diameter at thick end, measured with bark. Based on the experience of others, first of all from Russia, the Baltic and Scandinavian countries, it is known that wood greenery represents valued raw material in different sectors of economy: agriculture, pharmaceutical and cosmetics industry, and others. The entire annual attack of wood greenery remains unused, with us. There are two reasons for this: a) because there are still no elaborated and proven practices of rational collection and concentration of raw materials to processing plants; and b) because we are not familiar enough with the methods of wood greenery processing. A detailed analysis of the technology of wood assortment production in our forestry practice has been carried out. Based on these findings, a model of integrated forest utilization was conceived, including wood greenery. Then, the technology of wood greenery processing was analyzed in the following ways: mechanical drying and fractionation processes, chemical extraction processes, thermal processes by classical heating and energy use of the microwave electromagnetic field and their combinations: mechanical-chemical methods and thermo-chemical methods. Finally, such technology of wood greenery processing has been selected to optimally matches with the integrated use of forest resources, in terms of the following criteria: minimal negative environmental impact, maximum safety at work, low energy consumption, primarily from renewable sources, maximum quality of final products.

Keywords: *wood greenery, processing technology, forest dendromass*

Introduction

Wood greenery (WG) consists of branches with needles or leaves with a diameter of up to 10 mm measured over bark from the butt end (Fig. 1); it is also referred as technical greenery. WG is made from brushwood of coniferous and hardwood trees. WG is a raw material for the production of several products, with a variety of usable values such as: vitamin-mineral flour, chlorophyll - carotenoic paste, essential oils, fitoinsecticides, phytopharmaceuticals, plant growth regulators, primary forms of medicinal preparations in human medicine etc. (Vučić *et al*., 2019).

In our forests, around 2.94 mil. m^3 of dendromass is cut down each year. Of these, about 4-6% or 117,000 to 176,000 m^3 makes WG (Ljubojević *et al*., 2007). The entire annual attack of WG remains unused, with us. There are two reasons for this: a) because there are still no elaborated and proven practices of rational collection and concentration of raw materials to processing plants, and b) because we are not familiar enough with the methods of WG processing.

Figure 1: Wood greenery of fir (*Abies alba* Mill.); (photo: S. Ljubojević)

The aim of the paper is to analyze the technology of production of wood assortments in our forestry practice and, based on this knowledge, to propose the concept of integral forest exploitation, which includes WG. Then to analyze the technologies of WG processing and to choose the solution that most completely satisfies the given criteria.

Material and method

The subject of research is WG of domestic conifers: fir (Abies alba Mill.), spruce (Picea excelsa Link.), Scots pine (Pinus silvestris L.) and black pine (Pinus nigra Arnold). In comparison to the raw material of the broadleaf (deciduous) species, the coniferous raw materials are of no seasonality and can be used throughout the year. An analysis of the production technology of wood assortments in our forestry practice was carried out by monitoring three felling areas in different harvesting season. The basic characteristics of the observed objects are given in Table 1. Harvesting and processing technology was observed using method of continuous timing during one full working day per felling area. In this way, a chronological sequence of work elements was established, from the moment when the cutting begin until the moment when the timber assortments are dispatched to the timber yard. Along with this, not disturbing the regular production process, three organizational solutions were tested.

1. WG was separated from the branchwood and brushwood at a felling site using simple garden tree shearing scissors, then put in 70 liters bags, loaded on pack-horses and carried to the storage place along the truck road.
2. Brushwood was separated from the branchwood at the felling site using axes and strong bypass lopper and than stacked in small bundles. From here the raw material was handed over to the iron baskets arranged along the skid road; in regular production these baskets are used for the transportation of stacked wood. Baskets were mounted on the front and rear of the skidder and forwarded to the storage place, where the finally separation of WG was carried out.
3. The third organizational solution was applied in a strip clear cut in pine plantation on a steep terrain, where it is not justified to build permanent roads (skidding trucks and forest

roads). The trees were cut and hauled as a whole or split by half, using pair of winches: „Ackja“ winch for skidding from stupms to the ropeway and „Gantner HSW 20“ winch for extraction down the mainline.
WG was separated from the branchwood and brushwood by hand tools at the and of the ropeway.

Table 1: The basic characteristics of the observed objects

Basic characteristics	Observed objects

Harvesting system	Assortment method	Assortment method	Full-tree method
Appearance form of wood greenery (WG)	WG integrated with branchwood - at felling site	WG integrated with branchwood - at felling site	WG integrated with branchwood - at timber yard

To better understand the working conditions on preparation of WG, the average moisture content by the tree species and the felling season was determined, in the usual way and based on small samples ($ni \leq 30$). For the same reasons, the bulk density of WG was evaluated as well. With that regard, a wooden container of 1 x 0.5 x 0.5 m was made. It was filled with material to the top and weighed on the field scale, with a reading of 0.1 kg. The obtained values are converted to the standard unit kg/m3.
By inspecting the scientific and professional papers, technical documentation and patents, processing technologies of WG have been analyzed and a solution that satisfies the following criteria has been selected: a) a mass-usable product is produced without further fractionation, b) waste that is generated during production is usable, c) production takes place without the use of chemical agents, d) production is flexible with respect to raw material origin - it is possible in mobile and stationary plants, f) selected solution is proven in practice. Also, chosen solution does not adversely affect the environment, provides all the necessary safety at work and requires low energy consumption, primarily from renewable energy sources.

Results and Discussion

To make WG a kind of raw material, it is necessary to conduct several working operations: to collect branchwood from the felling site, to separate WG from the branchwood and to gather it in a form suitable for transportation, to transport it to the processing site. In doing so, we distinguish between internal transport, on a move from stumps to the storage place, and external transport, from the storage place to the processing plant. Collecting WG from standing trees is not reasonable for reasons that need not to be specifically explained. On the contrary, the only possible solution is the separation of the tree's greenery immediately after the tree felling in any sitations: regular felling, sanitation felling, random yield etc.

Manual preparation of wood greenery

In a typical case, manual preparation of WG involves four work elements: 1. collecting brunchwood left behind after cutting the trees, 2. separation of WG from brunchwood, 3. carrying of WG to the containers for transport, 4. stacking of WG at the containers for transport. The following average working time structure was determined for the implementation of the described work elements in the eighth hours working day (WD): Effective working time (EWT) - 6 h (75% of WD), Delay time (DT) - 2 h (25% of WD), where under the EWT we mean a period of useful work, and under the DT allowed breaks in work, such as: meal time, rest and personal time, interference time. The following average structure of EWT was determined: Preparatory time – 14.4 min (4% of WT), Time of transition (from tree to tree) - 24.8 min (8% of WT), Separation of WG from branchwood - 277.2 min (77% of WT), Disposal and stacking of WG at the container - 39.6 min (11% of WT). Average production rate per worker was determined as 161.4 kg of WG per WD, with variation interval: 134 - 189 kg of WG per WD. These results point to the conclusion that manual preparation of WG is not economically justified due to the low productivity.

Internal transport

Relatively high moisture content in fresh WG and its low bulk density (Tab. 2) make it difficult to find rational solutions with the transport means currently in use in our forestry, whether the raw material is carryng from the forests in bags on pack-horses, or in iron baskets mounted on the skidder. The only economically viable solution is to transport entire trees using wire-rope systems. However, this technological solution rarely meets our forestry practice, and as a such, it does not have a decisive significance in the eventual organization of mass production. Conversely, mechanical hauling of whole trees or parts of them is not acceptable due to the high pollution and damage of raw material (Ljubojević, 2008).

Table 2: Moisture content in fresh wood greenery and its bulk density

Harvesting season	Tree species			
	Scots pine	Black pine	Fir	Spruce
Moisture content (%)				
Winter	51	51	50	48
Summer	51	53	50	47
Bulk density (kg/m^3)				
Winter/summer	57,6	82	142	173,2

Concept of primary collection and concentrations of wood greenery to the processing site

An applicable techno-economic solution assumes the mechanized gathering and palletizing of forest residues in the form of biomass bundles and their delivery to the processing plants (Il. tab. 1, production lines 1 and 2; Ljubojević, 2016). In this way, it significantly shortens the time of primary collection and concentration of raw material to the processing site, ensures better raw material quality and at the same time increases the bulk density of the load. Two-stage separation of biomass is performed at the processing site. In the first step, branchwood and brushwood are separated by a light hydraulic crane. Branchwood is directed to the production of solid biofuels (woodchips, briquettes, pellets). Brushwood is mechanically separated into ligno-cellulose

1	Logging residues at the felling site	Making bundles with the slash bundler at the felling site	Collecting bundles over felling site and transfering to the storage place	Transporting bundles to the processing plant
				
2	Logging residues at the felling site	Collecting and transporting forest residues to the storage place	Making bundles with the slash bundler at the storage place	Transporting bundles to the processing plant
				

Illustrated table 1: Production lines for bundling of logging residues in regular felling skeleton and wood greenery. Separation of WG from the wooden skeleton is the most important operation in the phase of WG preparation. By switching from manual to mechanized production, it significantly increases productivity and reduces production costs (Hakkila, 1989; Levin et al., 1984; Nikitov, 1985). Separator "ODZ-12A" is an automatic machine constructed and introduced into regular production in the former USSR (Tomčuk and Tomčuk, 1966). The separator consists of five basic parts and mechanisms mounted on a rigid chassis: 1. belt conveyor (internal), 2. roller inserter, 3. roller ejector, 4. separation drum with blades, 5. bunker for receiving WG. Automatic feeding of separation drum with WG and discharge of bare branches is carried out by belt conveyor. Top layer of belt consists of metal rolls with welded ribs - a thin cylinders in the form of non-head nails. Its working position and strength is regulated by tensile rowels. Drum with blades is the main part of separator. It devides green parts from wooden skeleton by means of knives fixed with clamps. Rubber shock absorbers prevent collisions during rotation. External belt conveyor inserted WG in a shape of brushwood into the separator, piece per piece with a thicker end forward. Main technical characteristics of the separator are: capacity - 1.5 t WG/h, separation purity - 98%, power - 3.8 kW, drum rotation speed 500 - 650 /min, working volume of bunker - 0.5 m^3.

Choice of optimal wood greenery processing technology

WG serves as a raw material for obtaining a large number of products with a wide usage value, for which various technological processes have been developed (Tab. 3). Fresh unprocessed branches with needles are used as a protective cover for young agricultural crops, soil protection from moisture loss, as an addition to fodder and as a raw material for compost production (Duryea and Edwards, 1997; Daugavietis et al., 2015). When domestic animals and poultry are fed, a previous smoothing with water vapor is practiced.

If the simplified review of processing technologies is filtered through the set of criteria, the production of vitamin-mineral flour (VMF) comes out as an optimal solution. VMF can be produced in mobile facilities and in stationary plants, both of which operate according to the same principles (Hakkila, 1989; Levin et al., 1984; Nikitov, 1985; Tomčuk and Tomčuk, 1966). Only exception is WG of fir which, due to the high content of essential oil, requires additional technological intervention, combining hydrodestillation with short-term processing of the raw material by high pressure steam (so-called steam cracking) (Levdanskij et al., 1992).

Table 3: Simplified review of wood greenery processing technologies

Products obtained from wood greenery	Essence of the processing technology	Source
Vitamin-mineral flour	Thermal and mechanical treatment by combining drying, sorting and grinding processes	Hakkila (1989), Levin (1984) Nikitov (1985), Tomčuk (1966)
Essential oils	Hydrothermal treatment by aqueous distillation	Daugavietis (2014), Tomčuk (1966)
BAC* of law molecular weight	Chemical treatment by extraction with aqueous sodium hydroxide solution**	Karmanova (2005), Terenteva (2016) Šanina (2004)
BAC* of high molecular weight	Thermochemical treatments	Karmanova (2005), Terenteva (2016)
Chlorophyll-carotenoic paste	Thermohemical treatment by gas extraction process in combination with distillation of essential oils	Levin (1984), Tomčuk (1966)
Primary forms of medicinal preparations in human medicine	An infusion in water or in diluted ethanol; coniferous therapeutic extract	Levin (1984), Paršikova (2015)

*Biologically Active Compounds
**This process yields more useful products. Lipids are used in perfumes, medicine and other industries. Concentrate of neutral ingredients (provitamin concentrate), separated by emulsion extraction, can be used as a bioactive additive in the perfumery and cosmetic industry and as an additive in domestic poultry and cage breeding fur animals.

Production of VMB is carried out according to the following procedure (Tomčuk and Tomčuk, 1966; illustration No. 17): WG from the collecting bunker drops onto the screw conveyor which brings it to the crusher. Rough chips comes out of the crusher as a mixture of needles and particles of wood and bark. It is carried through conveying duct by compressed air into the bunker. At the bottom of the bunker there is a dosing unit by which rough chips is evenly distributed to the first drying column. A mixture of greenery and particles of wood and bark floats in the column space. Stream of hot air is programmed so that only the hardest fraction (particles of wood) can fall down. This fraction is collected into the container below the first drying column, from where it is periodically inserted into the furnace. From the first column, the dried material goes to the second and the third column for further drying. A part of the material that is not sufficiently dried and, therefore is heavier, is separated and via feedback sent for redrying. Completely dried material goes through the cyclone and the dosing unit to the mill in which it turns into flour. It passes through a sieve of 1.5-2 mm diameter and through conveying duct goes to the cyclone with WMF bunker and with line for filling and sewing bags with VMF. Bare branches falls into the press for briquettes which are intended for market or used on-site for own needs. Compared with mentioned plant, Hakkila (1989) describes a slightly smaller, more compact and more mobile chip sorter "SIKO-2". Recently, processing of WG into VMF using the energy of the microwave electromagnetic field, have been described by Posmetjev and Latiševa (2018). The essence of this process is to convert the energy of the microwave electromagnetic field into the heat. According to the authors, with applying their solution one can achieve separation purity of 90-95 % by weight without prior mechanical processing (as made by „ODZ 12A" separator). Unfortunately, this solution has not yet lived in practice, inspite the fact that it has been officially patented in 2007 (Posmetjev *et al*.).

Conclusions

So as to become a raw material, it is necessary to conduct several operations over WG: to gather branchwood from the felling site, to separate WG from branchwood, to gether it in a form suitable for transport and to deliver it to the processing site. Manual preparation of WG is not economically justified due to the low productivity. Relatively high moisture content in fresh WG and its low bulk density make it difficult to find rational solutions with the transport means currently in use in our forestry, whether the raw material is carryng from the forests in bags on pack-horses, or in iron baskets mounted on the skidder. The only economically viable solution is to transport entire trees using wire-rope systems. However, this technological solution rarely meets our forestry practice, and as a such, it does not have a decisive significance in the eventual organization of mass production.

An applicable techno-economic solution assumes the mechanized gathering and palletizing of forest residues in the form of biomass bundles and their delivery to the processing plants. In this way, it significantly shortens the time of primary collection and concentration of the raw material to the processing site, ensures better raw material quality and at the same time increases the bulk density of the load.

Separation of greenery from the wooden skeleton is the most important operation in the phase of preparation. By switching from manual to mechanized production, it significantly increases productivity and reduces production costs.

Of the many products that can be obtained from WG, VMF is especially distinguished as a mass-consumable product in the feeding of domestic animals. Its production is flexible in relation to the source of raw materials - it is possible in mobile and stationary plants, and waste generated during production is usable. Production takes place without use of chemicals and any negative impacts on environment.

ECONOMIC ASSESSMENT OF THE WATER ECOSYSTEM SERVICE PROVIDED BY FOREST AREAS WITH WATER PROTECTION FUNCTIONS IN NORTHWESTRN BULGARIA

Nevena SHULEVA*, Paula MALKOVSKA

University of Forestry, Sofia, Bulgaria
*Corresponding author: shuleva.nevena@gmail.com

Abstract
The EU Biodiversity Strategy for 2020 (2011) adopted by the European Commission recommends that Member States map and assess the state of ecosystems and their services in their national territory, assess the economic value of such services, and promote the integration of these values into supervisory and reporting systems at EU and national level. The Bulgarian legislation (Forestry Act, 2011) defines 9 paid services provided by forest areas, as well as the possibility that certain forest areas be designated in regional development plans as areas providing paid ecosystem services. The money collected from these payments are going to be divided among the owners of the forest areas – territorial units of forest and hunting holdings, municipalities, etc. The question should be answered: what a fair income the forest owner should receive from the water protection function as a part of the gross added value created in the country's water sector. The purpose of the latest study is to make an economic assessment of the water ecosystem service provided by forest areas with water protection functions of two municipalities in the North-West region in Bulgaria. The results show that about 2.5% of the cost of water that is used and paid for by water users and water-producers must be given to forest owners. When the water is used for irrigation, the cost of the ecosystem service is 0,007 BGN for 1 m^3 water, for electricity production - 0,003 BGN for 1 m^3 water and for drinking needs - between 0,018-0,026 BGN for 1 m^3 water.

Keywords: *Ecosystem services, Economic assessment, Forest areas, Bulgaria*

Introduction
The importance of ecosystems, their services and sustainable use for long-term human well-being is being increasingly recognised (MA 2005, TEEB 2010). The EU Biodiversity Strategy for 2020, adopted by the European Commission recommends that Member States map and assess the state of ecosystems and their services in their national territory, assess the economic value of such services, and promote the integration of these values into supervisory and reporting systems at EU and national level. (European Commission 2011)
The importance (value) of ecosystems and their services can be expressed in different ways but basically, there are three value domains: biophysical, socio-cultural and economic (Groot et al. 2010, Martín-López et al. 2014).
The Bulgarian legislation (Forestry Act) defines 9 paid services provided by forest areas, as well as the possibility that certain forest areas be designated in regional development plans as areas providing paid ecosystem services. The money collected from these payments are going to be divided among the owners of the forest areas – territorial units of forest and hunting holdings, municipalities, etc. (Forestry Act, 2011)
In Bulgaria, 85% of the water resources are derived from mountain catchments where forests are the predominant type of vegetation, and 60% of irrigable areas are irrigated by water coming from forest catchments. Forest areas provide water resources that account for 60% of the demand for drinking water. (Yovkov, Shuleva, 2011)
The forest areas with water protection functions in Bulgaria cover an area of 248,943 ha, which equals 6.1% of the forest fund. 72.64 % of these territories are state land, 11.41% -

municipal land, 9.89% - private land, and 6.06% - other land. Forests with water protection functions accumulate between 1-1.5 billion m3 of water annually. These forests play the role of a multi-annual equalisation tower which provides an all-year-round uniform flow of presumably clean water, which is brought to water consumers and water users through aquaculture facilities.
In order to obtain this product, the forest owners are obliged to manage them in a special regime. In the water protection regime, the goal is not to get wood from the forest, but to manage it in order to preserve or even increase the water protection systems and water regulating natural properties of forest ecosystems. Every forest owner would only manage his forest as a water protection if he could get income from that property. Such type of management is possible, if the water protection properties of the forest ecosystems become a function of production for the forest owners. The institutions should protect investment in water protection forests so that each forest owner is able to calculate his future incomes through water use and water consumption chain. The question should be answered: what a fair income the forest owner should receive from the water protection function as a part of the gross added value created in the country's water sector. (Yovkov, Shuleva, 2011)
The purpose of the latest study is to make an economic assessment of the ecosystem service „water", provided by forest areas with water protection functions of two municipalities (Varshets, Berkovitsa) in the North-West region in Bulgaria.

Material and Methods

To determine the economic assessment of the water ecosystem service provided by forest areas with water protection functions, the following methodology is used:
1. Determining the reserve of standing wood (V) of the tree species, included in the structure of the plantation, m^3;
2. Determining the current annual growth by volume of the available stand of trees ($Z_v^{тек}$), m^3;
3. Assortment of the timber from current growth;
4. Determining the cash value of the current growth ($Wz_v^{тек}$), BGN;
5. Determining the present value of the permanent costs (FVv), BGN;
6. Determining the net financial contribution of the plantation (NFC) BGN, based on the following formula:

NFC = $Wz_v^{тек}$ – FVv, BGN/hectare,

where: $Wz_v^{тек}$ is the cash value of the current growth for a 10-year period, BGN;

FVv – present value of the permanent costs of production, BGN

7. Determining the rate of return (profit) (RR), % based on the following formula:

$$RR = \frac{NFC}{Wv - Wz_v^{тек}}.100\,,\ (\text{в } \%)$$

RR – rate of return (profit) on investment;
NFC - net financial contribution (NFC) per 1 hectare, for a certain reserve of the stand of trees, BGN/hectare

$Wz_v^{тек}$ - the cash value of the current wood growth for a 10-year period, BGN/hectare;

W_v – the cash value of the reserve of the stand of planted trees, BGN/hectare.
8. Determining the cost of the ecosystem service „water" (CES), BGN for the respective municipality, based on the following formula:

$$\boldsymbol{CES} = RR * P_W^D Q_W^D + RR * P_W^I * Q_W^I + RR * P_W^E * Q_W^E ,$$

where RR is the rate of return (profit) on investment, %;

P_W^D – average market price of drinking water, BGN/m^3;

Q_W^D – quantity of drinking water used per 1 year, m^3;

P_W^I – average market price of irrigation water, BGN/m^3;

Q_W^I – quantity of irrigation used per 1 year, m^3;

P_W^E – average market price of electricity, BGN/KW;

Q_W^E – quantity of water used for the production of electricity per 1 year, m^3;

Results and Discussion

Economic assessment of the water ecosystem service provided by forest areas with water protection functions in the scope of the Varshets Municipality

The forested area of the forest territories in the scope of the Varshets Municipality, which provide the ecosystem service "water" is 1084,4 hectares, which accounts for 9,45 % of the total area of the forest territories in the municipality. The average age of the plants is 104 years, average reserve - 247 m^3/hectare, and the average growth is 2,96 m^3/hectare. The beech is the most common tree species - 987,3 hectares or 91 % of the total forested area (Table 1)

Table 1. Allocation of the forest areas by wood types and estimated productivityof the forest territories in the scope of the Varshets Municipality, providing the ecosystem service "water"

Wood species	Forest area (hectares)						Average
	I P	II P	III P	IV P	V P	Total	Productivity
Beech	51,5	325,9	491,6	104,1	14,2	987,3	2,7
Other	40,7	12,6	33,2	9,6	1,0	97,1	2,7
TOTAL (hectares)	92,2	338,5	524,8	113,7	15,2	1084,4	2,7

*Source: Forest management project of TEF "Petrohan"

The average productivity of all forests, providing the ecosystem service "water" on the territory of the Varshets Municipality is 2,7. The plantations with Average Productivity II account for 50% of the forested area or 524,8 hectares. The prevailing plantations of the VIII class of age (over 140 years) - 499 hectares or 46 %.

The average market price of the timber sold by TEF "Petrohan" in 2018 year are: for deciduous tree species - Large Construction Timber /LCT/ - 111,84 BGN/m3, Medium Construction Timber /MCT/ - 75,47 BGN/m^3, Small Construction Timber /SCT/ - 74,07 BGN/ m^3 and Wood - 65,07 BGN/m^3; for coniferous tree species - LCT - 86,29 BGN/m^3, MCT - 60,00 BGN/m^3, SCT - 47,00 BGN/ m^3 and Wood - 50,00 BGN/m^3.

The results of the separate elements of the methodology for the calculation of the Net Financial Contribution (NFC) are presented in Table 2.

Table 2. Evaluation of the Net Financial contribution of 1 hectare of beech – estimated productivity III on the territory of the Varshets municipality

*Source: Author's calculations.

The economic evaluation of the forest territories, ensuring the ecosystem service „water" on the territory of the Varshets Municipality shows that the largest financial contribution per 1 hectare of beech, which accounts for 91% of the area is 307,59 BGN/year and it is obtained with reserve of the stand of trees – 226 m3/hectare. The rate of return (profit) is 2,59%.

Table 3. Water users and water consumers from the Varshets Municipality

Water Supply and Sewerage operator	Cost of Water BGN/m^3	Cost of Energy BGN/kWh	Cost of Ecosystem Services at RR=2,59% BGN/m^3
"ViK"OOD- Montana	1,01		0,026
"Napoitelni Sistemi"AD, Sofia	0,26		0,007
"ENERGO-PRO Sales" AD		0,13476	0,003

*Source: Accounts of Companies

On the territory of the Varshets Municipality the water users and water consumers will have to pay a price for the ecosystem service „water" between 0,003 and 0,026 BGN for 1 m^3 water consumed (Table 3)
The total cost of the ecosystem service „water" for the Varshets Municipality was calculated based on the following formula:

CES = $0{,}0259*1{,}01*Q_W^D + 0{,}0259*0{,}26*Q_W^I + 0{,}0259*0{,}13476*Q_W^E$,

where P_W^D is average market price of drinking water, BGN/m^3; Q_W^D – quantity of drinking water used per 1 year, m^3; Q_W^I – quantity of irrigation used per 1 year, m^3; Q_W^E – quantity of water used for the production of electricity per 1 year, m^3;

Economic assessment of the water ecosystem service provided by forest areas with water protection functions in the scope of the Berkovitsa Municipality
The forested area of the forest territories in the scope of the Berkovitsa Municipality, which provide the ecosystem service „water" is 6902,2 hectares, which accounts for 32,77 % of the total area of the forest territories in the municipality. The average age of the plants is 112 years, average reserve - 285 m^3/hectare, and the average growth is 2,96 m^3/hectare. The beech is the most common tree species - 5864,4 hectares or 85 % of the total forested area (Table 4)

Table 4. Allocation of the forest areas by wood types and estimated productivity of the forest territories in the scope of the Berkovitsa Municipality, providing the ecosystem service "water"

Wood species	Forest area (hectares)						Average Productivity
	I P	II P	III P	IV P	V P	Total	
White pine	6,9	64,6	93,7	83,2	0	248,4	3,0
Spruce	202,6	51,9	86,5	21,7	7,6	370,3	1,9

Other	67,1	73,7	123,9	121,2	33,2	419,1	3,0
TOTAL (hectares)	745,0	3117,9	2207,5	617,6	214,2	6902,2	2,5

*Source: Forest management project of SOF "Berkovitsa"

The average productivity of all forests, providing the ecosystem service „water" on the territory of the Berkovitsa Municipality is 2,5. The plantations of Productivity II and III account for 77% of the forested area. The prevailing plantations of the VIII class of age (over 140 years) – 2630,6 hectares or 38,11 %.

The average market price of the timber sold by SOF "Berkovitsa" in 2018 year are: for deciduous tree species - LCT - 111,84 BGN/m^3, MCT - 75,47 BGN/m^3, SCT - 74,07 BGN/ m^3 and Wood - 65,07 BGN/m^3; for coniferous tree species - LCT - 86,29 BGN/m^3, MCT - 60,00 BGN/m^3, SCT - 47,00 BGN/ m^3 and Wood - 50,00 BGN/m^3.

The results of the separate elements of the methodology for the calculation of the Net Financial Contribution (NFC) are presented in tables 5,6,7.

The economic evaluation of the forest territories, ensuring the ecosystem benefit „water" on the territory of the Berkovitsa Municipality shows that the largest financial contribution per 1 hectare of beech is 415,40 BGN/year and it is obtained with reserve of the stand of trees - 291 m^3/hectare, for the white pine - 153,25 BGN/year at 243 m^3/hectare and for the spruce - 325,21 BGN/year at 376 m^3/hectare. The average rate of return (profit) is 2,54%.

Table 8. Water users and water consumers from the Berkovitsa Municipality

Water Supply and Sewerage operator	Cost of Water BGN/m^3	Cost of Energy BGN/kWh	Cost of Ecosystem Services at RR=2,54% BGN/m^3
"ViK - Berkovitsa" EOOD	0,71		0,018
"Napoitelni Sistemi"AD, Sofia	0,26		0,007
"ENERGO-PRO Sales" AD		0,13476	0,003

*Source: Accounts of Companies

On the territory of the Berkovitsa Municipality the water users and water consumers will have to pay a price for the ecosystem service „water" between 0,003 and 0,018 BGN for 1 m^3 water consumed (Table 8).

The total cost of the material ecosystem service „ensuring the quantity and quality of water" for the Berkovitsa Municipality was calculated based on the following formula:

$$CES = 0{,}0254*0{,}71*Q_W^D + 0{,}0259*0{,}26*Q_W^I + 0{,}0259*0{,}13476*Q_W^E$$

Conclusions

In general, forests and forest areas with water protection functions have real owns and management organizations. The water management function of forests is between 25% and 100% in the multipurpose management target models. The realization to these target models in market economy conditions should be linked to the contribution of each individual investment, incl. and water-related functions. In order to trigger a new price mechanism for the implementation of water management function it is necessary to consider forests not just as a fund (accumulation) but to obtain public recognition of capital. Investing in forests with varying degrees of plumbing in pluralistic ownership has the character of acquiring assets with different yields. The state's constitutional law on water resources does not prevent it from entering into a public-private partnership with the various forest owners. It is also not an obstacle to the economic forestry organizations that it has set up to allocate in the form of a rent income a part of the gross added value of the water business organizations. Moreover, the recognition of market character relation between water-borne forests and water consumption can reduce the pressure on the use of wood. This pressure is now becoming more and more significant and damaging to the water functions of forests. Impacts, water scarcity, impaired drainage modules of forest ecosystems in the period since 1997 are those empirical facts that point to institutional changes in the direction of acquisition of a productive nature of the water protection function of forests and economic assessment of the ecosystem service "water".

PLANNING THE SIZE OF SAMPLE PLOTS IN THE RESEARCH MACEDONIAN PINE STANDS IN THE STRICT NATURE RESERVATE "MALI BELEG" IN SOUTH SERBIA

Aleksandar POPOVIĆ*

Faculty of Forestry, University of Belgrade, Belgrade, Serbia
*Cooresponding author: aleksandar.popovic@sfb.bg.ac.rs

Abstract

Determining the size of the sample plots is a demanding and complex issue and it depends largely on the character of the planned research. The approach of defining the stands as a set of trees was respected in this paper. Methodological procedure on the dendrometric-statistical basis was fully applied. Planning the size of the sample plot started from choosing an optimal number of trees in it using the classical statistical formula to determine the sample size. In even-aged, pure stands of Macedonian pine, optimal number of trees was analyzed on the basis of the predefined level of accuracy and the variation of their properties. In the pre-investigation process the coefficient of volume variation (CV%) was 78.59% based on 145 measured trees at a elementary test surface of 0.20 ha. The density of the stand is determined on the basis of 30 test surface. The optimal number of 371 trees was determined according to the usual level of the desired accuracy of volume determination ($\pm$8%). The size of sample plot of 0.58 ha was established using the principles of proportionality. Derived values can vary within the determined accuracy of the estimated density stand of $\pm$9.10%. The value of the sample size had an orientational character. When determining the surface it was necessary to respect all the factors influencing the definition of the optimal real size of the sample plot.

Keywords: *Planning, sample plot, stand, Macedonian pine, south Serbia*

Introduction

Macedonian pine (*Pinus peuce* Griseb.) belongs to a group of relic, endemic, rare and endangered species of trees (Medarevic, 2006). In Serbia it is represented on a small area within its wider distribution along the mountain range Hajla-Stedim-Zljeb-Beleg-Pogled (Fukarek, 1949).

When researching forest ecosystems choosing adequate sample values is the starting point for successful achievement of the set goal. The problem of sample planning in our conditions is still underdeveloped areas even it has vital role in all aspects of forest management. Generally, forest inventory has an important role in forest management and it is providing necessary high-quality data from forest resources (Georgakis and Stamatellos, 2019). Therewith, sampling is a fundamental postulate of forest inventory (Kershaw Jr, Ducey, Beers and Husch, 2016). While planning a sample size, the basic principle is to achieve the highest precision (accuracy) of estimation at minimal cost (Koprivica, 2004). Sampling design balance between precision and cost constraints (Yang et al., 2017). According to all the difficulties of making decisions on small samples and uneconomical nature of large-sample research, the adequately established value of its size is one of the most significant segments. The procedures for determining the sample plot size are different in case of investigating the characteristics of stands. Sampling may take one of two forms: subjective sampling (experientially) or probability sampling (objectively) (Gyde Lund and Thomas, 1989). Sometimes using statistical sampling is justified in combination with subjective ones (Cunia, 1982). The theory of probability sampling refers to the basic rules of determining them. The basic values that make up a sample depend on its design and refer to the layout, size and number of repetitions. Specific sample size planning solutions have been applied in some studies (Bankovic, 1981; Koprivica, 2004; Pantic, 2002). The paper examined the adequate size of the field (sample plot) in the Macedonian pine stands within the study site. As the subjective methods of establishing sample size are foreseen for short-term research (Gyde Lund and Thomas, 1989), the statistical sampling (probability theory) method has been applied in the paper with reference to the long-term plan for researching Macedonian pine stands.

Materials and methods

The study was performed in south Serbia, Strict Nature Reservate (SNR) of Macedonian pine forest "Mali Beleg" (Figure 1).

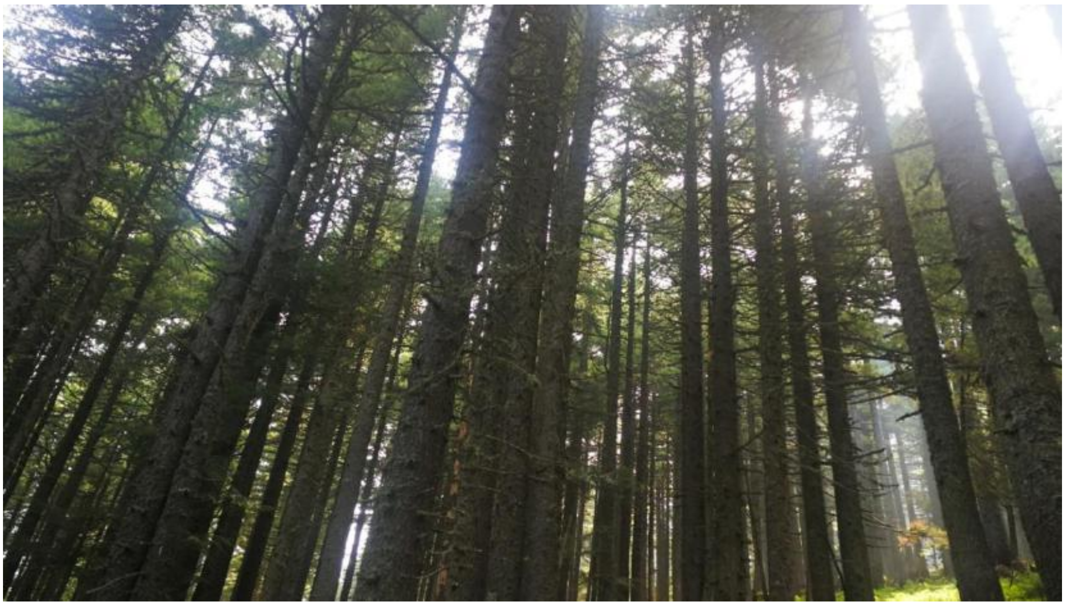

Fig.1. Natural pure stand of Macedonian pine in the SNR "Mali Beleg" (Photo: Popovic Aleksandar, 2019)

The combined statistical-dendrometric method of determining the optimal size of the sample plot was applied. In order to determine the optimal number of trees on the surface, classical formulas (1) were used to determine the size of a simple random sample (Freese, 1962; Hadzivukovic, 1991; Koprivica, 2015; Bankovic and Pantic, 2006).

$$n = \frac{t^2 \cdot CV_{\%}{}^2}{m_{\%}{}^2} \quad (1)$$

An approach was used to define a stand as a set of trees (Koprivica, 1999). The optimal set (number) spatially defined is determined on the estimated density of the stand.

The variation of the characteristics of trees is defined according to 145 trees within an elementary test surface of square shape (0.20 ha). This is based on fact that application of classical formulas requires knowledge of the variability of taxation elements in advance. The values of the optimal number of trees were determined by the coefficient of variation of diameter ($d_{1.3}$), height (h), basal area (g) and volume (v) of individual trees at different levels of desired accuracy ($m_x \rightarrow 5\%$, 8% and 10%). Tested accuracy levels are common and regularly used in forestry researches. Their value depends on the importance and intensity of researches. Tree volume values were determined based on two-way table (Parisko, 1962).

In order to determine the density of the stand *($N \cdot ha^{-1}$)*, 30 test surfaces of a circular shape with a constant surface of 0.05 ha were measured (Figure 2). Surfaces were set up within a predefined target group of stands. There were included pure, even-aged, closed, dense and very dense canopy (0.7; 0.8-0.9; 1.0) stands. The circles were sampled on the principles of random sampling, and all that did not meet the requirements of canopy and mixability were not considered as adequate. The planned optimal sample plot area was determined based on proportionality principles concerning the previously determined optimal number of trees.

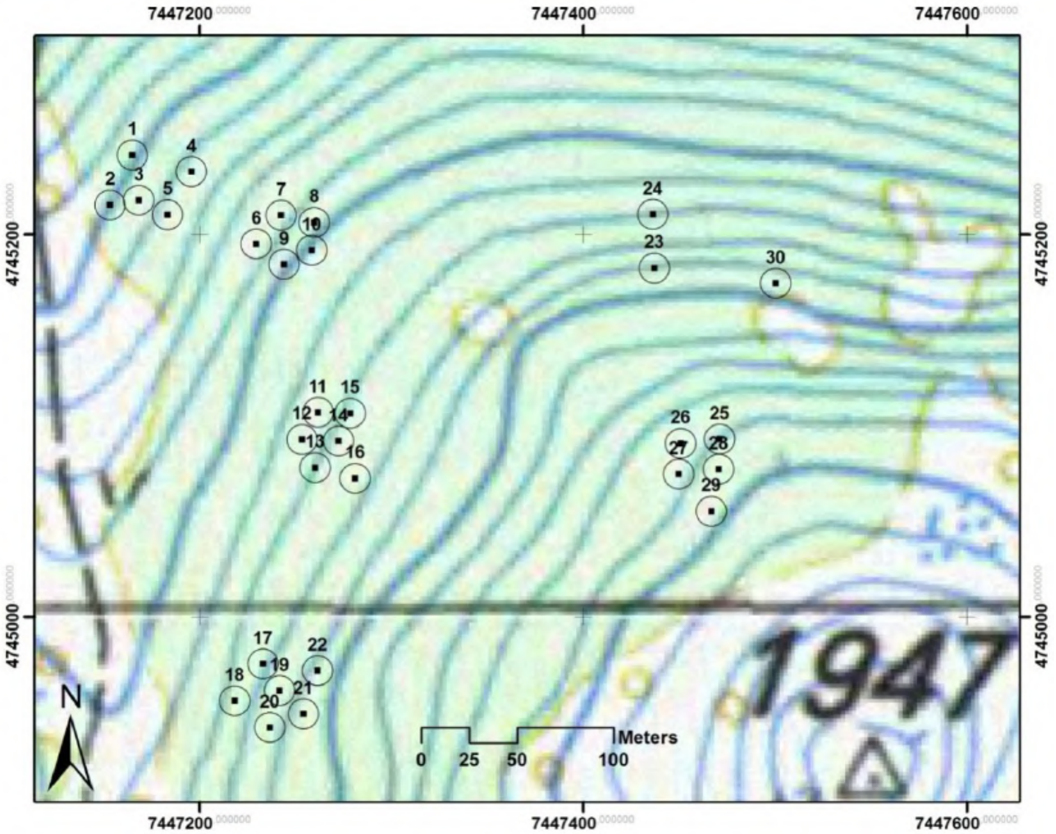

Fig. 2. Random sample test surfaces in pure stands in SNR "Mali Beleg"

According to the formulas for a simple random sample, the relative error of the arithmetic mean (2) of the characteristics of the trees and sampled surfaces was determined:

$$m_{\%} = \frac{CV_{\%}}{\sqrt{n}} \cdot t \quad (2)$$

wherein the:

$m_{\%}$ - relative error of arithmetic mean ($\pm$ in %)

$CV_{\%}$ - coefficient of variation of the studied sample properties (in %)

t - table value (n-1 and 95%)

Descriptive statistics methods in the appropriate software package were applied for the purpose of data processing.

Results and discussion

The elementary test surface was set in slope conditions at an average slope of 22°, north-western exposure (298°), and an altitude of 1.820 m. The stand is pure, dense canopy (0.8-0.9) with even-aged character. The stand has a rainforest character due to its strict protection regime and it was selected as a representative sample of the investigation stands. The average number of trees on the surface is 725 $N \cdot ha^{-1}$.The tree sample has the following statistical parameters (Table 1) of the variation of their characteristics.

Tabela 1. Statistical indicators characteristic of Macedonian pine trees (d, h, g, v)

Descriptive Statistics	**$d_{1.3}$ (cm)**	**h (m)**	**g (m^2)**	**v (m^3)**
Mean	30.47	15.69	0.0821	0.6597
Std. Error of Mean	0.9021	0.2924	0.0046	0.0430
Std. Deviation	10.86	3.52	0.0554	0.5185
Variance	118.00	12.40	0.0031	0.2688
Coef. of Variacion (%)	35.64	22.43	67.47	78.59
Minimum	10.55	4.20	0.0087	0.0356
Maximum	57.40	22.30	0.2586	2.2500
Sum	4,419.00	2,275.00	11.90	95.65

The mean value of the established diameter is 30.47 cm, and the height is 15.69 m. The maximum established diameter is 57.40 cm, and it's height is 22.30 m. The largest variation is shown by the volume values of individual trees, which is 78.59%. The value of the coefficient for the ratio of the variation of volume to diameter in the investigated stand is 2.20. The obtained value corresponds to the established regression relations in previous studies (Hlavcek, 1965 in Koprivica, 1999). The established basal area on the elementary test surface is 11.9 m^2 (59.50 $m^2 \cdot ha^{-1}$) and the volume is 95.65 m^3 (478.25 $m^3 \cdot ha^{-1}$).

Based on a sample of 30 circular test surfaces, the average density of the stands in the reservate was determined. The sample has the following statistical characteristics (Table 2) of the number of trees.

Table 2. Statistical indicators of trees number (*N*) characteristics from test surfaces *(TS_{30})*

Statistics Descriptive	*$N(TS_{30})$*
Mean	31.9
Std. Error of Mean	1.4234
Std. Deviation	7.79

Variance	60.77
Coef. of Variacion (%)	24.43
Minimum	21
Maximum	49
Sum	957

The average number of trees on area of 0.05 ha is 31.9, determined according to the sample with a coefficient of variation of 24.43%. On a total surface area of 1.5 ha, 957 trees were identified, where average is 638 $N \cdot ha^{-1}$. The number of trees on the surfaces ranges from 21 (min) to 49 (max).
The differences in the values of the average number of trees from the surfaces (87) are due to the different shapes and size of the samples on which they were determined.
In order to conduct the research with a known level of statistical significance, relative errors of arithmetic means of the studied taxation characteristics were determined on the basis of the starting sample (Table 3).

Table 3. The relative error of determining the arithmetic mean of the sampled trees

Standard Error of Mean (± %)	**Characteristics of trees**			
	$d_{1.3}$	**h**	**g**	**v**
P=95%; **n=144;**	5.80	3.28	10.98	12.79

The largest error in the arithmetic mean was found at value (±12.79%), as expected due to the largest variation in the volume of individual trees. The smallest value obtained is the relative error of height estimation (±3.28%), which is ± 0.51 m in absolute values. The relative error of mean diameter is ±5.8% (±1.76 cm).
The relative error of determining the average number of trees based on a sample of 30areas at a significance level of 95% is ±9.10%. It is ±58 trees on estimated amount of 638 $N \cdot ha^{-1}$. The estimated density stands is in the range of 580 to 696 trees per hectare. The values determined this way will form the basis of the calculation of optimal surface of the sample plot.
The established error values are within the limits that can be considered as acceptable according to character of the research. Therefore, the sample can serve as a reliable basis for determining the optimal number of trees on the sample plot (Table 4).

Table 4. Optimum number of trees calculated on different basis and levels of desired accuracy

Optimal number of trees on the sample plot ($N_{opt.}$)				
$m_{x\%}$	Basis of calculation			
	$d_{1.3}$	**h**	**g**	**v**
5	195	62	700	949
8	76	24	273	371
10	49	16	175	237

The smallest values were determined on basis of height (16, 24, 62), while the highest values were obtained on volume basis (949, 371, 273). Values were determined in the target at different levels of desired accuracy ($m_{x\%}$).

Considering that the primary precision is to determine the volume, the basis for calculating the optimal surface was the determined by value of this parameter. The area was determined on the ration of the determined number of trees per hectare and the optimal number of trees according to the coefficient of variation (volume) of individual trees (3) at different levels of desired accuracy ($m_{x\%}$).

$$P_{opt.} = N_{opt.(V)} / N \cdot ha^{-1} \quad (3)$$

$P_{opt.} = 1.49\ ha$ (m_x=5%)

$P_{opt.} = 0.58\ ha$ (m_x=8%)

$P_{opt.} = 0.37\ ha$ (m_x=10%)

Derived values can vary within the determined accuracy of the estimated density stands of $\pm$ 9.10%.

Conclusion

The paper establishes indicative values of the size of the sample plot in order to estimate the volume of pure and even-aged stands of the Macedonian pine at SNR "Mali Beleg". The determined surface values vary depending on the desired level of accuracy of the estimated results. At the level of 5% the area ranges from 1.36 ha to 1.63 ha. At the usual level of accuracy volume estimates in Serbia of 8% the area ranges from 0.53 ha to 0.64 ha. At the level of accuracy of 10% it ranges from 0.34 ha to 0.41 ha. In order to estimate the average diameter, it is necessary to measure from 49 to 193 diameters and to estimate the mean height it is necessary to measure from 16 to 62 heights.

The values obtained for estimating the mean height stand are relatively low what is a consequence of the low height variation as an expression of specific stand and habitat conditions. The values have orientational character and are related to the target group of stands at the studied site. In addition to the determined values of the sample size, it is necessary to determine the schedule and the necessary number of repetitions when forming the optimal plan of the experiment. The mentioned values depend on the purpose of future research and that was not the subject of this paper.

While deciding the final sample size, different factors must be included that affect the successful implementation of the research. This particularly refer to financial frameworks which limits every research. The obtained values are applicable only within the given frameworks and conditions of the researching stands of the Macedonian pine in the SNR "Mali Beleg".

VARIABILITY OF CONCENTRATION OF PHOTOSYNTHETIC PIGMENTS IN LEAVES OF SYCAMORE MAPLE (*Acer pseudoplatanus* L.) ONE-YEAR-OLD SEEDLINGS OF DIFFERENT HALF-SIB LINES

Vladan POPOVIĆ*, Ljubinko RAKONJAC, Aleksandar LUČIĆ

Institute of Forestry, Belgrade, Serbia
*Corresponding author: vladanpop79@gmail.com

Abstract

The variability of concentration of photosynthetic pigments in leaves of Sycamore maple (*Acer pseudoplatanus* L.) one-year-old seedlings was studied at the level of 11 half-sib lines in the seedling nursery conditions. Three types of pigments have been examined: chlorophyll a, chlorophyll b and carotenoids. Their concentration at the level of the half-sib lines as well as the interdependence was determined. The seedlings were produced in the seedling nursery of the Institute of Forestry in Belgrade (Serbia) in equal environmental conditions and from the seed of known origin. The leaf sampling was carried out in the middle of the growing season. The highest average value of chlorophyll a (0.878 mg/g) was determined in the half-sib line 9, and the lowest in the half-sib line 7 (0.496 mg/g). The highest average value of chlorophyll b (0.952 mg/g) was determined in the half-sib line 5, and the lowest in the half-sib line 11 (0.568 mg/g). The highest average value of carotenoids (0.462 mg/g) was determined in the half-sib line 9, and the lowest in the half-sib line 8 (0.197 mg/g). The strongest interdependence was determined between carotenoids and chlorophyll b (R^2 =0.0053), and the weakest between carotenoids and chlorophyll a (R^2 =0.0005). The researches have shown that the concentration of the photosynthetic pigments in the Sycamore maple leaves changes depending on the origin, or in this case the mother tree. The conclusion arising from the obtained results is that during the selection of mother trees the attention has to be paid to concentration of the photosynthetic pigments in leaves and the intensity of the photosynthesis because that will significantly affect the elements of seedlings' development.

Key words: *Sycamore maple, half-sib line, photosynthetic pigments, leaves.*

Introduction

The Sycamore maple (*Acer pseudoplatanus* L.) is the species that has been present on European continent since glacial (Svenning, J.C., Skov, F., 2004, 2005). It is widespread in parks as a decorative species. Forest plantations of Sycamore maple are rare in Serbia (Isajev, V., Mančić, A., 2001). As in their studies stated Ivetić, V., Tucović, A. (2003), "...the analysis of the variability of trees within the species in nature (Jovanović, B., 1967) and cultivated stands (Bojović, S., 1989) has been conducted since 1985 and for that reason this species lagging behind other species in terms of scientific researches...". Forestry as a science pays greater attention to studying the Sycamore maple in recent years.

Importance of photosynthetic pigments is reflected in the absorption of light necessary for the process of photosynthesis in plants. Chlorophylls are the primary photosynthetic pigments. They reflect green part of the spectrum of visible light, while carotenoids reflect yellow, orange or red part of the spectrum. The ability to absorb certain wavelengths of light is more important for the process of photosynthesis than the ability of reflection of the part of the light (Popović et al., 2015). Due to different size and shape as well as different concentration of pigments, the leaves have different ability to absorb visible light and to transform it into energy of chemical bonds (Čivić et al., 2003). A foliar concentration of the main photosynthetic pigments chlorophyll **a** and **b** is considered to be a bio-indicator of the total primary production of biomass (Gitelson, A., Merzlyak, M. N., 1994).

Bearing in mind that beside transforming light energy into organic compounds the concentration of the photosynthetic pigments affects the dominant coloration of higher plants, and increased adaptability of trees and stands, and is important as a raw material for pharmaceutical industry, so the knowledge on variability within the species is of increasing importance (Mataruga et al. 2000). The determination of the concentration of the photosynthetic pigments in leaves is justified because the intensity of photosynthesis depends greatly on it and also significantly influences the growth and development of seedlings.
The aim of the research in this paper is to determine how the origin of the seed which the seedlings were produced from affects the concentration and variability of photosynthetic pigments in the leaves of the Sycamore maple (*Acer pseudoplatanus* L.) one-year-old seedlings.

Material and Method

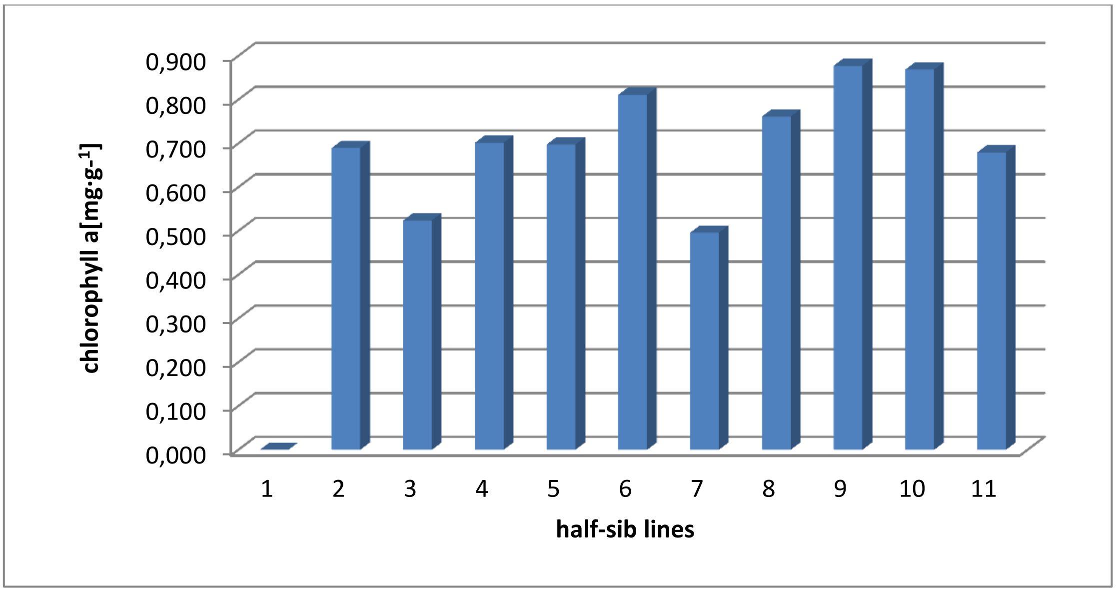
The seedlings were produced from the seed collected from micro-populations on the territory of Belgrade (Serbia). The seed was stratified by putting in cold, moist in sand for 5 months and in that way prepared for the spring sowing. The sowing was conducted in April 2016 in the seedling nursery of the Institute of Forestry in Belgrade (Serbia), in a hotbed size 1x10 meters. The space between rows in the hotbed is 15 cm, and the rows are parallel with the longer side of the hotbed.
Leaf sampling of Sycamore maple seedlings was conducted in the last week of July 2017. A sample of 1 g was homogenized using a mortar and pestle. For better homogenization of the sample 2 g of quartz sand was added in the mortar before mechanical grinding. The paste was for 3 minutes treated with 15 ml of 80% acetone. To this mixture was added 1 mg of $MgCO_3$ in order to prevent acidification of the solution. The resulting green solution was applied by a small glass rod on a glass filter and using a water spray vacuum pump it was filtered into the vacuum test tube. The resulting filtrate was the pigment extract which is transferred from the test tube to the regular 25 ml vessel and supplemented with 80% acetone to the line. To perform reading in a spectrophotometer the obtained extract has to be diluted. 1 ml of the obtained extract was taken by pipette and into that was added 9 ml of acetone and then it was transferred to the test tube. Thus prepared extract was poured into the cuvette and read on the spectrophotometer, the absorption was at the wavelengths 662, 644 and 440 nm. The formula of Holm and Wetsttein was applied to calculate the concentration of the pigment in the extract in mg / dm^3.
Preparing and reading on the spectrophotometer as well as calculating was performed using standard methods (Oljača and Srdić, 2005).

Results and Discussion

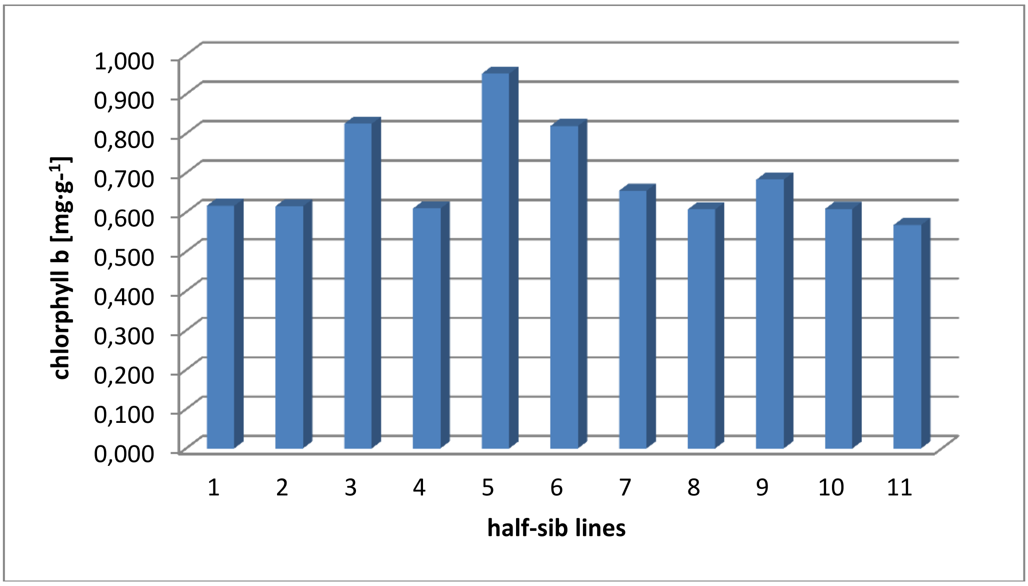
The review of the concentration of photosynthetic pigments in the leaves of the one-year-old Sycamore maple seedlings as per half-sib lines is shown in the Table 1 and Graphs. Based on the results can be concluded that the concentration of photosynthetic pigments changes depending on origin of the seed. The highest average value of chlorophyll a (0.878 mg/g) was determined in the half-sib line 9, and the lowest in the half-sib line 7 (0.496 mg/g). The highest average value of chlorophyll b (0.952 mg/g) was determined in the half-sib line 5, and the lowest in the half-sib line 11 (0.568 mg/g). The highest average value of carotenoids (0.462 mg/g) was determined in the half-sib line 9, and the lowest in the half-sib line 8 (0.197 mg/g).

Table 1. The concentration of photosynthetic pigments in the leaves of the Sycamore maple seedlings as per half-sib lines

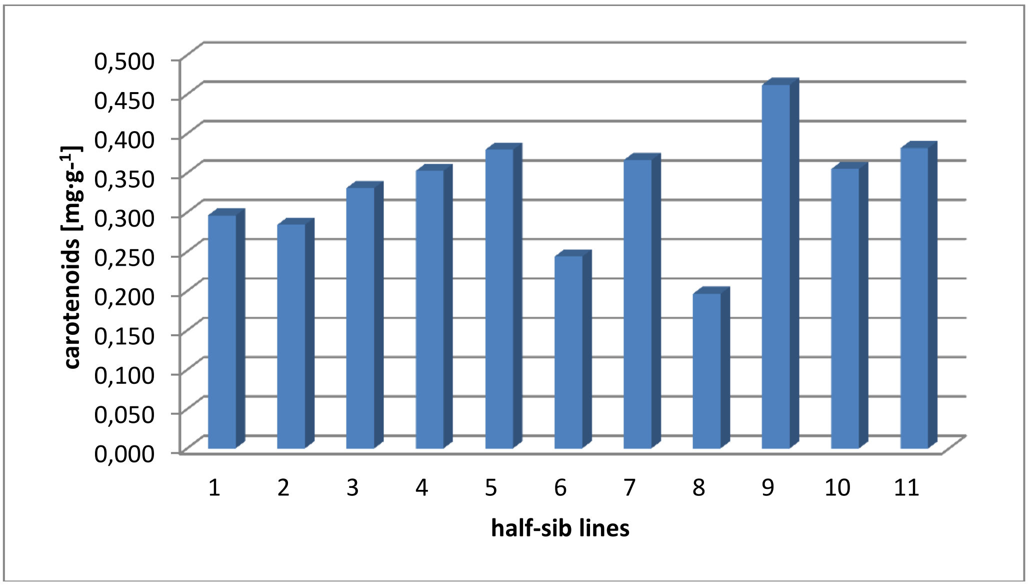
Half-sib line	Chlorophyll a mg/g	Chlorophyll b mg/g	Carotenoids mg/g
1	0.797	0.617	0.296
2	0.689	0.615	0.284
3	0.524	0.825	0.331
4	0.701	0.610	0.353
5	0.698	0.952	0.380
6	0.811	0.819	0.244
7	0.496	0.655	0.366
8	0.761	0.607	0.197
9	0.878	0.683	0.462
10	0.869	0.609	0.355
11	0.679	0.568	0.382



Graph 1. Concentration of chlorophyll a in leaves of Sycamore maple seedlings as per half-sib lines

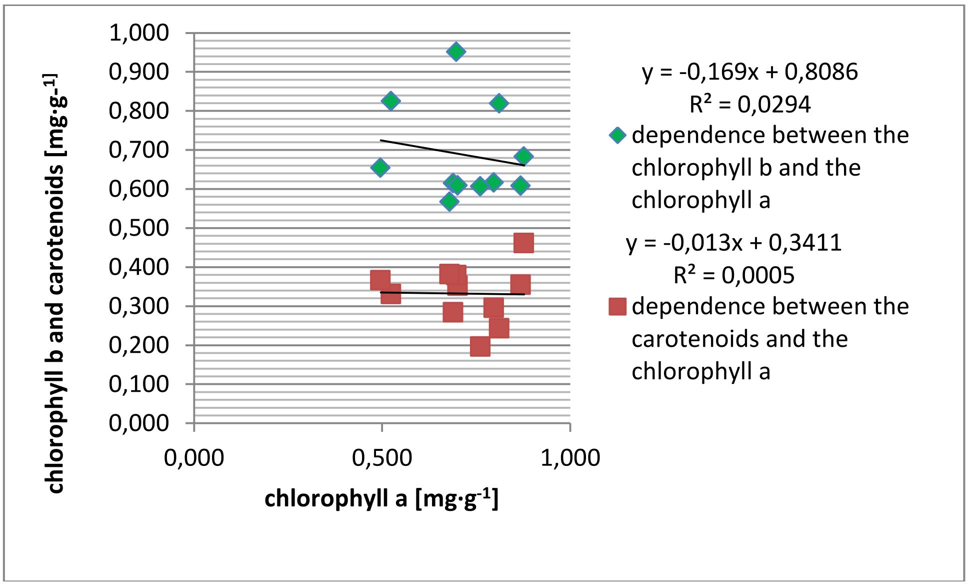


Graph 2. Concentration of chlorophyll b in leaves of Sycamore maple seedlings as per half-sib lines

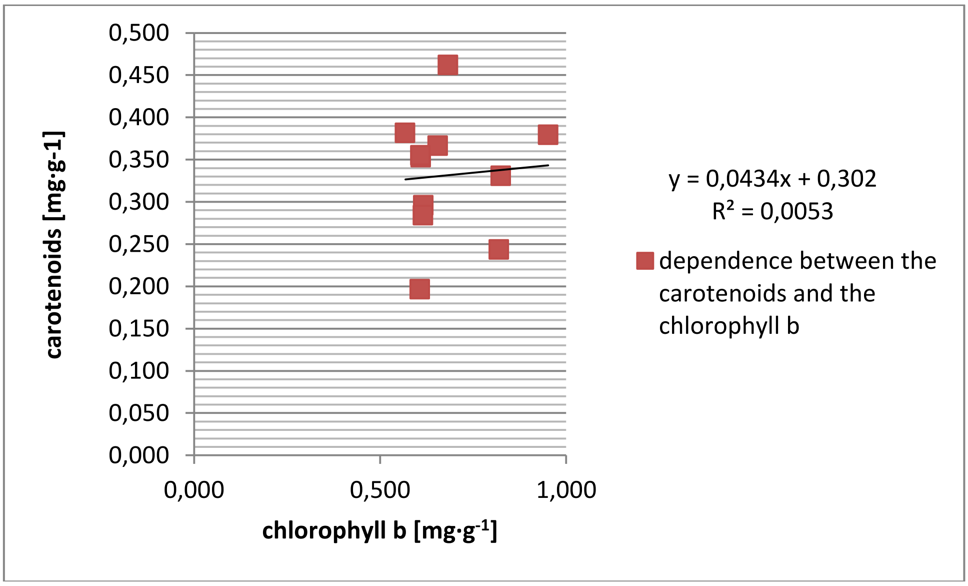


Graph 3. Concentration of carotenoids in leaves of Sycamore maple seedlings as per half-sib lines

The Graphs 4 and 5 show the interdependence of the studied photosynthetic pigments. The strongest interdependence was determined between carotenoids and chlorophyll b (R^2 =0.0053), and the weakest between carotenoids and chlorophyll a (R^2 =0.0005).



Graph 4. Dependence of the content of chlorophyll b and carotenoids on the content of chlorophyll a



Graph 5. Dependence of the content of carotenoids on the content of chlorophyll b

Given that the environmental conditions in the seedling nursery are equal, the determined differences in the concentration of pigments between seedlings of different half-sib lines are probably due to their genetic constitution. The existence of these differences can be used when selecting the best genotypes, mother trees, and breeding in general in order to maximize the use of the available gene pool of trees.

Conclusion

The obtained results have shown that the concentration of the photosynthetic pigments in the leaves of the Sycamore maple one-year-old seedlings changes depending on their origin. The significant amounts of pigments were found in the all analysed half-sib lines, but, as a rule, the woody plants have the surplus of pigments. The performed analyses confirm the paying attention to the physiological characteristics when selecting and using mother trees for the planned seed production. For a more comprehensive understanding of importance of knowing the concentration of pigments, it would be good to determine their concentration in different periods of growing season, as well as the interdependence of the concentration of pigments and the elements of seedlings' growth.

ANALYSIS OF YIELD QUALITY OF BALD CYPRESS (*Taxodium distichum* L. Rich.) AT THE LEVEL OF SEED STAND RS-2-2-tdi-00-240

Vladan POPOVIĆ*, Ljubinko RAKONJAC, Aleksandar LUČIĆ

Institute of Forestry, Belgrade, Serbia
*Corresponding author: vladanpop79@gmail.com

Abstract

Yield quality analyses of Bald cypress at the level of the seed stand RS-2-2-tdi-00-240 have been presented in the paper. Cones were collected from 20 mother trees evenly distributed throughout the seed stand. Further processing and yield quality analysis were evaluated in the laboratory of the Institute of Forestry in Belgrade (Serbia). . The following yield quality parameters were analyzed: coefficient of extraction, absolute seed weight, and technical germination in the field trial. The obtained results showed that average value of the coefficient of extraction per mother tree ranges from 13.14% to 17.38%. The absolute seed weight ranges from 96.5 g to 134.7 g and the technical germination ranges from 57.2% to 73.4%. The analyzed yield quality indicators are very important for planning nursery production because knowledge on these indicators can considerably influence the optimization of production costs. The analyzed yield quality indicators can also be used to assess the genetic quality of seed stand and to make recommendation for the transfer of seeds. The obtained results serves for improvement of mass production of high quality reproductive material of Bald cypress in Serbia and are good starting point for the future breeding program in forestry. .

Key words: Bald cypress, seed stand, yield, germination.

Introduction

Bald cypress naturally grows on flooded and periodically flooded soils in the southeast and Gulf areas of the United States, from Louisiana to Florida, Mexico and southeastern China. The Taxodium genus has been widespread in Europe and North America in the past. During the Holocene era in the Balkans was occurred numerous forest formations rich in species and valuable genetic resources (Alexandrov and Velkov, 2000). Some of these formations, originating from the Paleozoic era, were located in the Dinaric Alps, the Rhodope massif and a part of the Traki-Macedonian Mountains. The presence of the Taxodium genus (Palamerov, 1997) was recorded during the middle and late Oligocene era (Palamerov, 1997). Paleo-palynological examinations of pollen and spore samples from the wells in the Kolubara-Tamnava lignite basin showed that this area was within the wetland region, and the main representatives of forest vegetation were swamp conifers of the Taxodium genus and swamp broadleaves of the Nyssa genus (Dražić and Batos, 2002). The same research was conducted in the Rhine hard coal mine in Germany where the presence of identified species was determined with the domination of the species of the Taxodium genus. According to environmental and botanical characteristics the four species stand out on the stands in the natural area of distribution: *Taxodium distichum* L. Rich., *Taxodium ascendens* Brog., *Taxodium mucronatum* Ten. and *Taxodium heterophyllum* Brog. The first two species grow in USA, the third in Mexico, and the fourth in China.

It was introduced to Europe in 1640 on extremely humid soils and in areas with high underground or residual water. It is mostly grown as an ornamental species, but it can also be used for raising forest plantations (Vidaković, 1982). In Serbia mainly grows *Taxodium distichum* L. Rich. in the urban green areas (Belgrade, Novi Sad, Vršac etc.), although *Taxodium ascendens* Brog is also described in the park of Koviljaca spa (Tucović and Ocokoljić, 2005).

In the 1950s, Bald cypress as an allochthonous conifer species on the territory of the former Yugoslavia has come into focus of the professional public (Petrović, 1951; Špiranec, 1959). At the beginning of the 1970s, authors Tucović and Stilinović concluded that in our environmental conditions Bald cypress can be considered as a species of rapid growth, one of the rare coniferous species that can be suitable for introduction of conifers in lowland environments, and especially, flooded habitats where it can achieve high productivity. In Serbia, Bald cypress that grows in swamp plays an important role in horticulture where it is grown in groups or as soliter tree on wet terrains where other conifers fail.
The interest of the scientific community in Serbia for Bald cypress has been intensified recently, so the specificities and genetic variability of adult Bald cypress trees, as well as the characteristics of seeds and seedlings at the earliest stages of development have been recorded (Vukićević, 1987; Ninić-Todorović and Ocokoljić, 2001; Šijačić-Nikolić et al., 2011; Popović et al., 2012; Popović et al., 2012a; Popović et al., 2012b; Popović, V. et al., 2012c; Popović, V. et al., 2012d; Popović, V. et al., 2013; Popović, V., 2014; Popović, V. et al., 2014; Popović, V. et al., 2014a; Popović, V. et al., 2014b; Popović, V. et al., 2015;).
The aim of the study in this paper is to analyze the quality of Bald cypress (*Taxodium distichum* L. Rich.) yield at the level of the seed stand RS-2-2-tdi-00-240. The obtained results can serve for acquiring preliminary knowledge on genetic variability of the studied seed stand and for the improvement of the production of high quality seed and seedlings of Bald cypress in Serbia.

Material and Method

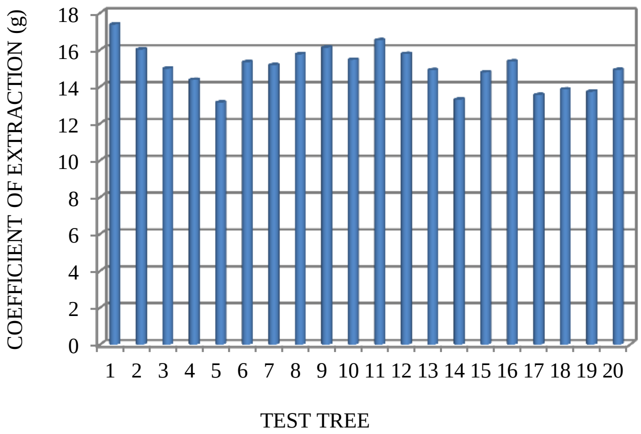
Cone sampling was performed in the seed stand RS-2-2- tdi-00-240 at the level of 20 test trees, 300 cones per tree were collected. The cones were manually harvested using hydraulic lifting platform and grouped into special bags for easier handling and proper monitoring of further studying. Afterwards they were transported to further processing at the Laboratory for Genetics, Seed Production, Physiology and Plant Breeding at the Institute of Forestry in Belgrade (Serbia). Fifty cones per each of 20 test trees were selected using a method of random sampling for the yield quality and cone processing analysis.The cones were then transferred to a dryer where they were heated at 40° C for 48 hours. After the cones opened the seed was separated by test trees. The absolute seed weight and the coefficient of extraction for each test tree were then measured. The weight of seeds and cones was measured on an electronic scale with an accuracy of 0.01 g.
In April next year the seed was sown in treset ???containers of type Bosnaplast 12 filled with the Tref TPS fine brown substrate in order to determine the field germination. The containers were disinfected before sowing with Benomyl solution. Four hundred seeds were sown per each test tree. The seeds were immersed in a citric acid solution of 100 ppm concentration before sowing and left to soak or to dry or in petri dish…please specify ??? for 48 hours. The temperature during germination was 18-20° C, and the germination rate was monitored for 28 days.

Results and Discussion

The values of the coefficient of extraction of 20 Bald cypress test trees respectively are shown in Table 1 and Graph 1. The coefficient of extraction is important in the process of planning the appropriate seed sampling rate. Coefficient of extraction stands for a quotient of the total seed weight and the total cone weight per one test tree. Correctly determined coefficient of extraction facilitates and ensures seed and seedling production. In addition to the production significance, it can also be used in determining the variability of the yield quantity between the test trees. The obtained results of the analysis shows variability of the coefficient of extraction between 20 Bald cypress test trees. The highest value of the coefficient of extraction was determined in the test tree number 1 (17.38%), and the smallest in test tree number 5 (13.14%).

Table 1: Coefficient of extraction

Test tree	Cone weight (kg)	Seed weight (g)	Coefficient of extraction (%)
1	3742	651	17.38
2	3540	567	16.02
3	4112	616	14.98
4	4322	621	14.37
5	3911	514	13.14
6	3424	525	15.33
7	3654	552	15.17
8	3821	602	15.76
9	4101	661	16.12
10	4082	631	15.46
11	3566	589	16.52
12	3621	572	15.78
13	3765	561	14.90
14	3828	509	13.30
15	4255	629	14.78
16	3910	601	15.37
17	4221	572	13.55
18	3992	553	13.85
19	4312	592	13.73
20	3898	581	14.91

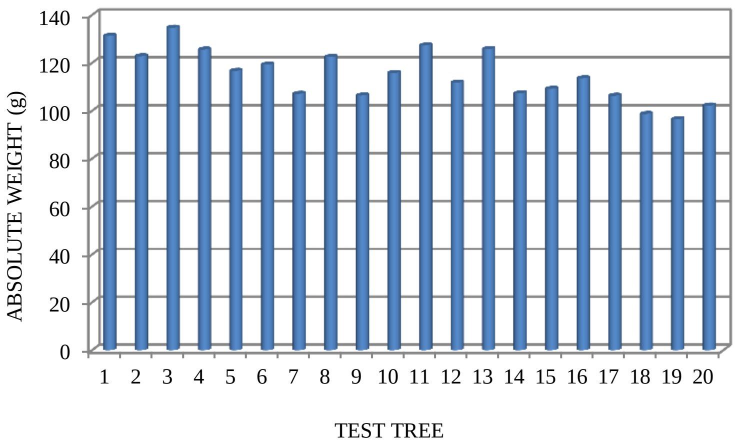


Graph 1: Variability of the coefficient of extraction

In the Table 2 and Graph 2 the values of the absolute seed weight at the level of 20 Bald cypress test trees were shown.

Table 2: Absolute seed weight

Test tree	Absolute seed weight (g)
1	131.3
2	122.8
3	134.7
4	125.6
5	116.7
6	119.3
7	107.1
8	122.5
9	106.4
10	115.8
11	127.3
12	111.8
13	125.8
14	107.3
15	109.2
16	113.6
17	106.3
18	98.7
19	96.5
20	102.2



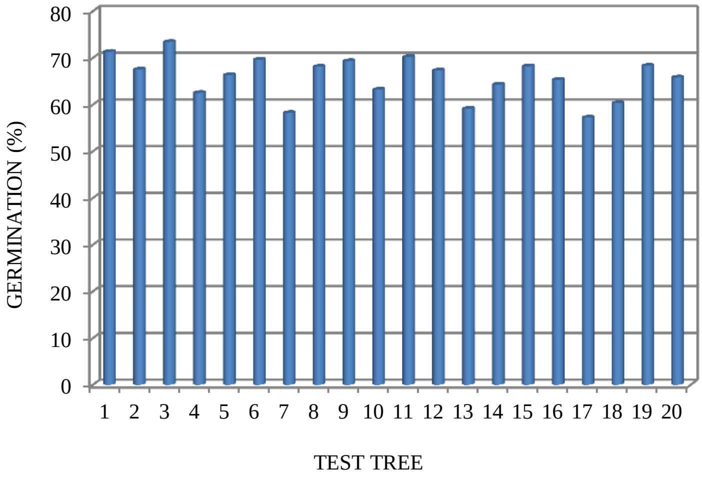
Graph 2: Variability of the absolute seed weight

The absolute seed weight is the weight of 1000 air-dried seeds expressed in grams. For the planning of nursery production, the knowledge of the absolute seed weight is of particular importance. In addition, it can be used to determine the variability of the yield quantity between the test trees, as well as the variability within population. The analysis of the obtained values of the absolute seed weight at the level of 20 Bald cypress test trees shows that the highest value was determined in the test tree number 3 (134.7 g), and the smallest in test tree number 19 (96.5 g).

Table 3 and Graph 3 show the values of technical germination in percentages at the level of 20 Bald cypress test trees. Knowing the percentage of seed germination is necessary when determining the sowing norm, and can also be used to determine the variability of the yield quality between the test trees. According to studies of many authors (Monk, C. D., Brown, T. W., 1965; USDA Forest Service, 1965, 1974; Faulkner, S. P., 1982; Gunderson, L. H., 1984; Krauss, K. W. et al., 1998) the natural germination of Bald cypress ranges from 2 to 15%. Stilinović, S. (1985) stated that in the conditions of Serbia the Bald cypress full-seed is up to 50%.

Table 3: Technical seed germination

Test tree	Technical germination (%)
1	71.3
2	67.5
3	73.4
4	62.5
5	66.3
6	69.6
7	58.2
8	68.1
9	69.3
10	63.2
11	70.2
12	67.3
13	59.1
14	64.3
15	68.2
16	65.3
17	57.2
18	60.3
19	68.3
20	65.8



Graph 3: Variability of technical germination

The analysis of germination at the level of 20 Bald cypress test trees showed that the germination ranges from 57.2% in the test tree number 17 to 73.4% in the test tree number 3. If these values compare with the literature data, it can be concluded that the studied test trees have germination above average. Such a high germination rate is probably the result of pre-sowing seed treatment. The seed was immersed in the citric acid solution of 100 ppm concentration for 48 hours before sowing (Popović, V. et al., 2012c). Based on the obtained results this pre-sowing seed treatment can be recommended in regular production of Bald cypress seedlings.

Conclusions

The research carried out in the seed stand showed that Bald cypress has been well adapted to the conditions of the habitat in this locality, and that the yield quality is mostly conditioned by climate factors. The obtained results indicate the high gene-environmental potential of Bald cypress at the level of the seed stand as well as the pronounced variability of the analyzed characteristics at the level of the test trees.

The conducted analyzes point to the satisfactory seed yield quality at the level of the seed stand, which represents a good starting point for the improvement of mass production of seed of this species in Serbia.

The applied pre-sowing seed treatment method, described in this paper, contributes to the increase of seed germination, and the development of the technology of production of planting material can in many ways contribute to the mass production of Bald cypress in Serbia.

Abstract

National Parks are natural areas that usually possess high ecological and cultural value. Their intact landscapes, the representativeness of their natural ecosystems and the high diversity of their biota give them outstanding ecological, aesthetic, cultural, educational and scientific values. They have high conservation value and attract numerous visitors aiming to experience nature. A recent project co-funded by the European Union and the Greek National Funds is AdVENt*: Augmented Visitor Experience in National Parks*, started in 2018 and has a 3-year duration. The AdVENt project aims to develop innovative applications to enhance visitors touring experience in protected areas of particular environmental interest and natural beauty, as well as the production of rich and technologically advanced multimedia content for their promotion, to highlight their natural wealth as a remarkable and attractive touristic product. More specifically, the project focuses on the mountain complex of the Region of Central Greece, which includes the National Parks of Oiti and Parnassos. Both areas host a remarkably diverse flora and fauna, while Mt Parnassos is considered as a hotspot of plant species diversity and endemism. Important archaeological sites like Delphi, major ski centers and popular hiking trails are combined with remarkable natural fir forests and other mountain habitat types and a rich endemic flora. It is noteworthy, that AdVENt project will create: a) a vascular plant database of the National Parks of Oiti and Parnassos, available to the scientific community and the general public, which is expected to promote research in the relevant fields of botany, ecology etc., b) an integrated Augmented Reality (AR) mobile application for enhancing the visitors touring experience and c) the development of cutting-edge technology for the visual identification of vascular plant species.

Keywords: *Vascular plants, Application, Augmented Reality, National Parks, Natura 2000.*

Introduction

Mediterranean Basin is characterized by high geomorphological and climatic heterogeneity and has been acknowledged as one of the 18 biodiversity hotspots worldwide (Blondel & Aronson, 1999). Mediterranean mountains host an especially high plant diversity and endemism, rendering them an ideal stage for biodiversity and biogeographical studies. The flora of the Mediterranean Basin includes approximately 25,000 species or nearly 30,000 species and subspecies (Médail, 2008), a fact that renders it the richest among regions hosting Mediterranean ecosystems.

Greece, located at the crossroad of three continents, namely Europe, Asia and Africa, is an important component of the Mediterranean Basin hotspot (Sainz Ollero, Moreno Saiz 2002; Martín-Brano et al. 2010). The largest part of Greece is characterized by a typical Mediterranean climate with mild, humid winters and hot, dry summers although differences can be found regionally or locally due to the diversity of its topography (Hobbs et al., 1995). It is noteworthy, Greece hosts a large variety of Mediterranean habitats included in the reference list of the Natura 2000 initiative with an outstanding biodiversity, which is well protected within the boundaries of Greece's National Parks. National Parks are natural areas that usually possess high ecological, aesthetic, cultural, educational and scientific values. They host a high conservation value and attract numerous visitors aiming to experience nature. The vascular flora of Greece comprises 5758 species and 1970 subspecies (native and naturalized), representing 6620 taxa, belonging to 1073 genera and 185 families (Dimopoulos et al. 2013, 2016). The endemic vascular flora of Greece includes 1459 taxa (22% of the total number of taxa in Greece), corresponding to 1,274 endemic species (22.1% of the total number of Greek species) and 450 endemic subspecies (22.8% of the total number of Greek subspecies) (Dimopoulos et al. 2013, 2016). In order to achieve an increased direct and vicarious experience of nature for visitors in Oiti and Parnassos National Parks, a recent project co-funded by the European Union and the Greek National Funds AdVENt (*Augmented Visitor Experience in National Parks*) started in 2018 and has a 3-year duration. The AdVENt partnership includes: a) the inDigital SA, Greece (Coordinator), b) Institute of Mediterranean and Forest Ecosystems, Hellenic Agricultural Organization ″DEMETER″, Greece, c) Research and Innovation Information Technologies ″ATHENA″, Greece and d) Organization for Sterea Ellas Greece.

Project area

The project focuses on the mountain complex of central Sterea Ellas, which includes the National Parks of Oiti (Fig. 1) and Parnassos (Fig. 2). These National Parks**,** include remarkable natural and cultural richness, such as hiking trails, dense fir forests, endemic and rare plant species, landscapes of special natural beauty, historical and archaeological sites, as well as popular tourist destinations (Delphi and Parnassos ski center).

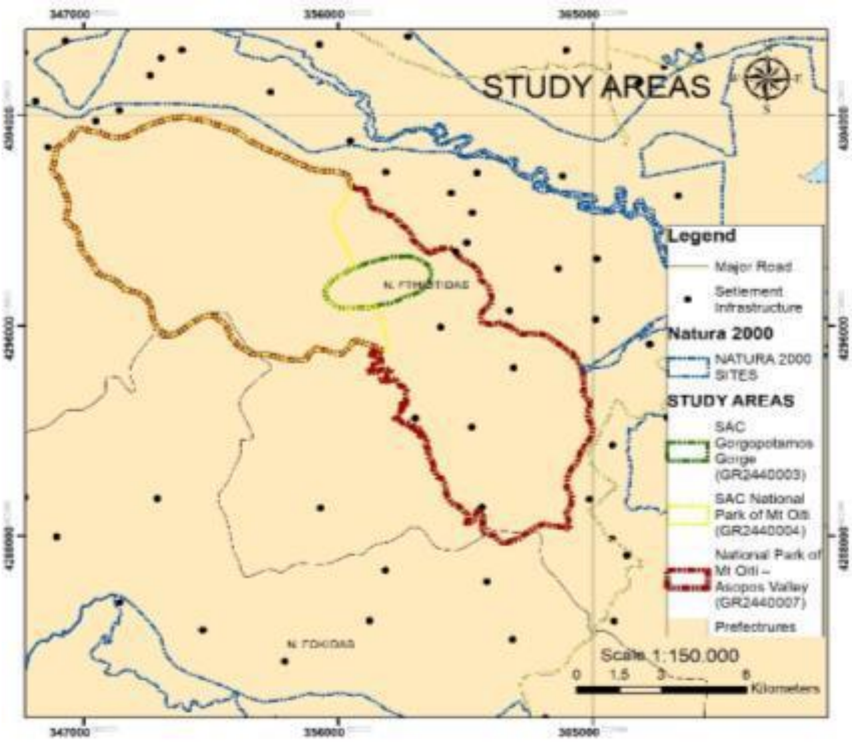

Figure 1. Oiti National Park (QGIS 3.6).

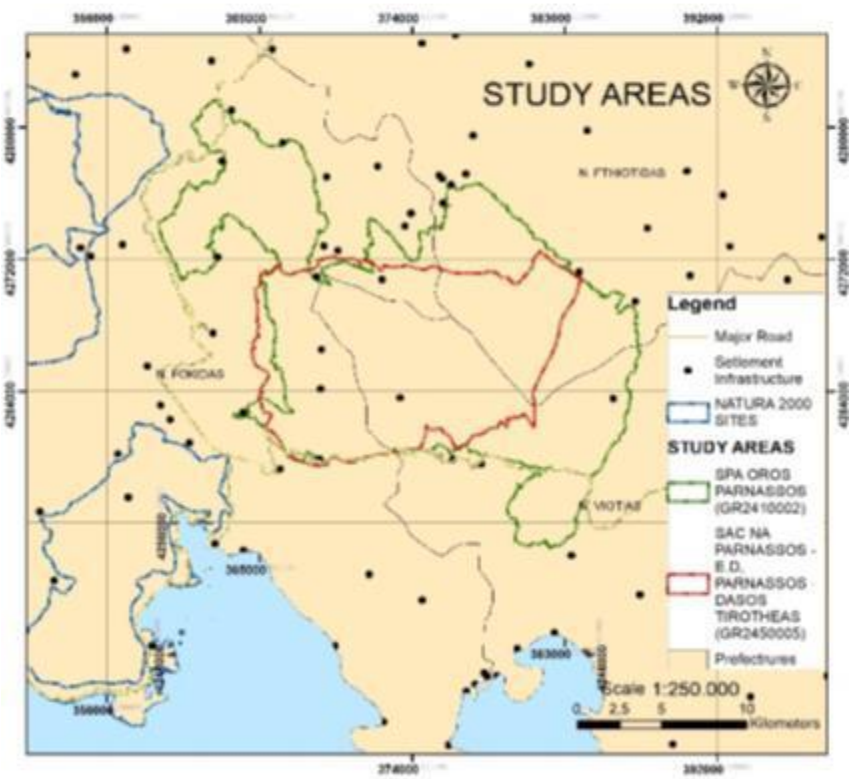

Figure 2. Parnassos National Park (QGIS 3.6).

Project objectives

National Parks of Oiti and Parnassos host a remarkably diverse flora, fauna and landscapes, while Mt Parnassos is considered as a hotspot of plant species diversity and endemism.

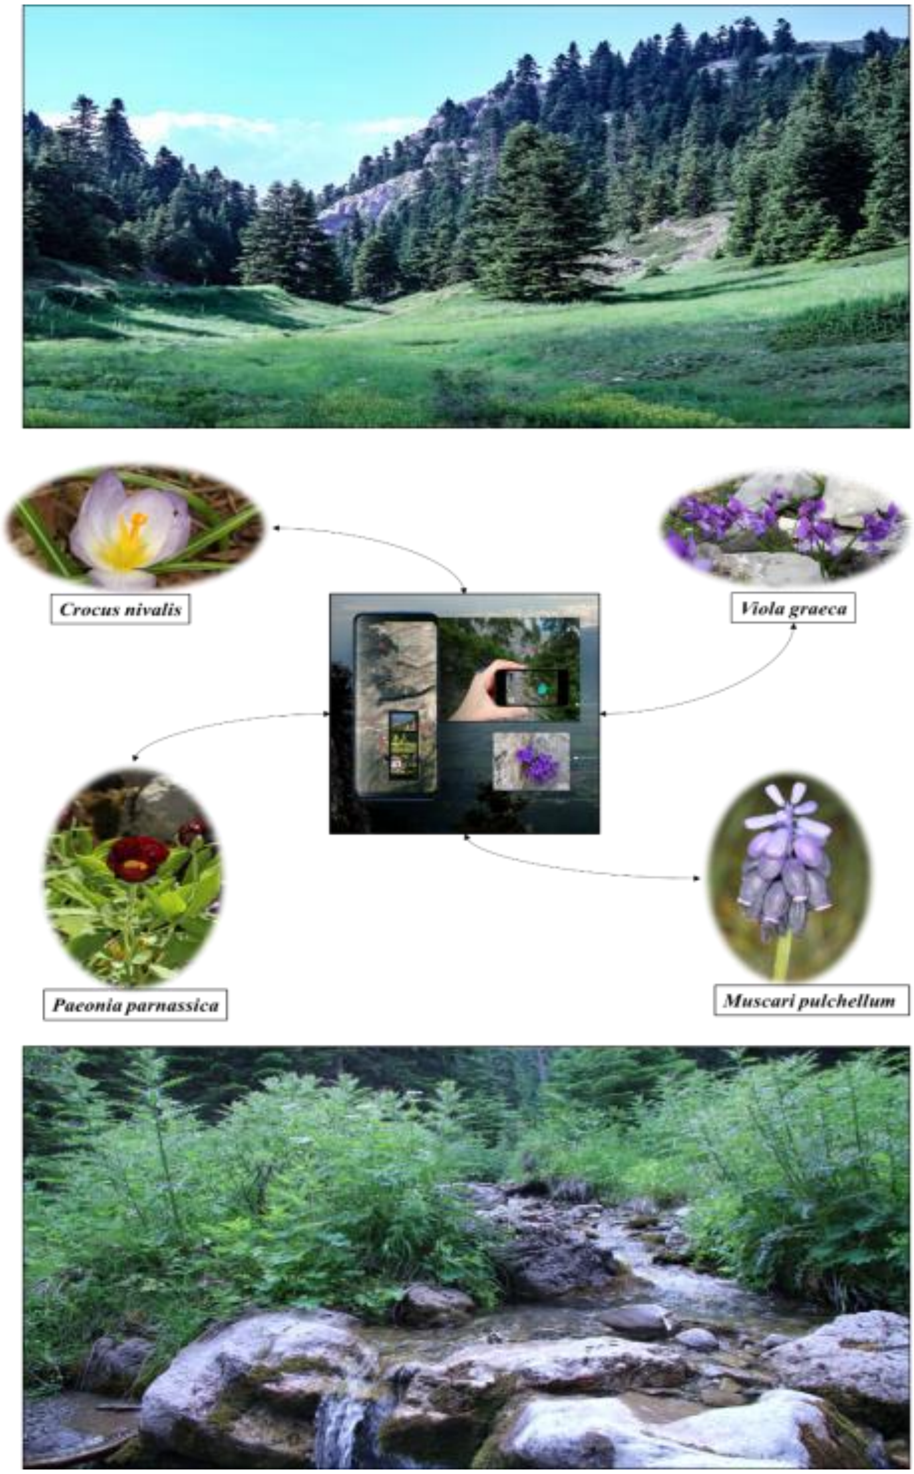

Figure 3. Visual identification of vascular plant species.

Mt Oiti, also known as the mountain of flowers and of legendary hero Hercules, is a mountain of unique beauty, with vast fir forests, rare as well as impressive plant species, rich fauna and abundant waters, which most of the times flow abruptly, through steep and beautiful gorges. It is the fifth highest mountain in Central Greece and its highest peak is Pyrgos (2.152 m) (Management Body of Oiti National Park, Sperchios Valley and Maliakos Gulf, 2019).
Also, Mt. Parnassos consists of spectacular cliffs and rocky areas. It mainly consists of hard limestones (76.6%), which forms particularly impressive karsts; some formations, such as the

Sinkhole of Lilaia and the Corycian Cave, are especially famous. Last but not least, Parnassos is a place of enormous cultural - historical heritage, i.e. the Sanctuary of Apollo and the Oracle of Delphi. In addition, the great cultural - historical value of the area is enhanced by the ancient and modern monuments, as well as the rich history of the region (Management Body of Parnassos National Park, 2019).
The main objectives of AdVENt project are the development of: a) a vascular plant database of Oiti and Parnassos National Parks, available to the scientific community and the general public, which is expected to promote research in the relevant fields of botany, ecology etc., b) an integrated Augmented Reality (AR) mobile application for enhancing the visitors touring experience and c) a cutting-edge technology for the visual identification of vascular plant species (Fig. 3). In addition, AdVENt aims to promote, enrich, and therefore enhance the visibility and competitiveness of the local tourism product.

Expected results

The first system of plant species identification in Greece is expected to be developed during AdVENt project. A cognitive database for the plant species of Oiti and Parnassos National Parks will also be created. This basis is going to be available not only to the scientific community, but also to the public and will contribute to knowledge enhancement of the relevant fields (botany, ecology etc.). The project will upscale and promote the applied research on the 3D digital illustration of natural areas at multiple spatial scales. Also, the sharing of the know-how between the enterprises and the research institutes will undoubtedly increase their competitiveness.
This project will unfold and provide innovative technological implementations suitable to underline the environmental wealth, natural beauty and cultural background of these specific mountainous areas. Creating thus, an attractive, modern touristic product with direct positive results and developmental possibilities for the local and also regional economy and society. In a way, the project will "equip" the local touristic product with a tool, which enriches the interaction of visitors with the natural environment, enhancing their overall experience. The idea of interacting and understanding the local culture of a place is very common among eco tourists who support the local economy preferring and advertising local produce and services.

Acknowledgments

This work is financially supported by the AdVENt project ″Augmented Visitor Experience in National Parks″ (T1EDK-03844) (https://advent.indigital.gr/), which is funded by the ″RESEARCH-CREATE-INNOVATE″ and co-financed by the European Union and Greek National Funds.

Abstract
The Mediterranean Basin is one of the most bio-diverse regions and the third most important plant diversity hotspot worldwide. However, the Mediterranean region is also known as one of the planet most threatened territories, being the 4th most significantly altered biodiversity hotspot of the planet, and the 2nd in habitat area loss. Therefore, one of the recent projects co-funded by the EC is LIFE17 NAT/GR/000511: "*Restoration, management and valorisation of PRIority habitats of MEDiterranean coastal areas*" (project areas: Anatoliki Makedonia – Thraki, Greece and Lazio, Italy). The primary aim of the project is to improve the conservation status of the habitats included in the Habitat Directive 92/43/EC: 1. Annex II (a) 3170* Mediterranean temporary ponds; (b) 91E0* Alluvial forests with *Alnus glutinosa* and *Fraxinus excelsior*; (c) 5230* Arborescent matorral with *Laurus nobilis;* 2. Annex I (d) 91M0 Pannonian-Balkanic turkey oak-sessile oak forests, as well as of the species included in the Annex I of the Habitat Directive 92/43/EC: (e) *Eurotestudo hermanni*, (f) *Emys orbicularis*, (g) *Callimorpha (Euplagia) quadripunctaria**, through interventions taking place within SCI GR1150010 and SCI IT6030022. It is noteworthy that the accurate and innovative interventions, that will be implemented in this project, can represent a good opportunity for conservation and restoration of biodiversity and ecosystem services, providing solutions for mitigating the climate change effects. Furthermore, the innovative interventions will be implemented and valorised during the project's duration so that replication and transportation to other similar environmental contexts will be feasible, thus promoting and enabling the long-term conservation of these habitats and species.

Keywords: *Restoration, Management, Valorization, Natura 2000, Mediterranean.*

Introduction
The Mediterranean Basin is one of the most bio-diverse regions and the third most significant plant diversity hotspot worldwide. It hosts 25,000 plant species, of which more than half are found nowhere else (Myers et al., 2000). However, this region is unfortunately known as one of the planet's most threatened territories, considered as the 4th most significantly altered biodiversity hotspots of our planet (Mittermeier et al., 2004) and the 2nd in habitat area loss. While, at the same time it has been identified has been identified as a climate change hotspot (Diffenbaugh and Giorgi, 2012). The observed seasonality in the distribution of temperature and precipitation is a characteristic of the Mediterranean climate. On the whole, there is a remarkable water stress in the species found in Mediterranean ecosystems due to hot and dry summers, while winters tend to be cool and wet.

We must take into consideration that thousands of years of human settlement and habitat modification have taken their toll. More specifically, rapid and abrupt land use changes due to agricultural land expansion or poor forest management technics including overexploitation, along with intensive grazing, frequent wildfires and infrastructure development, particularly in the coastal areas have contributed to the natural habitats' loss and degradation. Therefore, it is apparent, that habitat loss and degradation are mainly caused by human activities and pose as the main threat for the Mediterranean basin species. Extreme climatic events such as fires or severe droughts are expected to increase the threat further (Cuttelod et al., 2008). Hence, one of the recent projects co-funded by the EC is LIFE17 NAT/GR/000511: "*Restoration, management and valorisation of PRIority habitats of MEDiterranean coastal areas*", project areas: Anatoliki Makedonia – Thraki, Greece and Lazio, Italy) which will be contribute to improve the conservation status of the habitats. The project started in 2018 and has a 5-year duration.

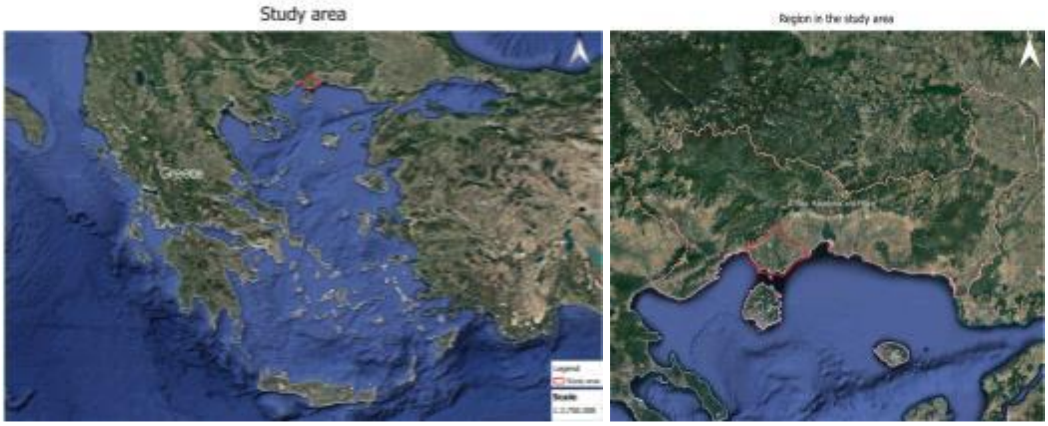
The LIFE PRIMED partnership includes: a) the Hellenic Society for the Protection of Nature (HSPN) (Coordinator), b) the Institute of Mediterranean and Forest Ecosystems, Hellenic Agricultural Organization "DEMETER", Greece, c) the Management Body of Nestos Delta - Vistonida - Ismarida, Greece, d) (i) the Department of Environmental Biology and (ii) the Department of Civil, Constructional and Environmental Engineering - Sapienza University of Rome, Italy, and e) the AGENZIA REGIONALE per lo SVILUPPO e l'INNOVAZIONE in AGRICOLTURA, Italy.

Project area

The LIFE PRIMED project is being carried out in the Nestos Delta, Kavala Greece – SCI GR1150010 [surface area (ha): 22,484.630] (Map 1) and in the Bosco di Palo Laziale [surface area (ha): 129.000] (Map 2).

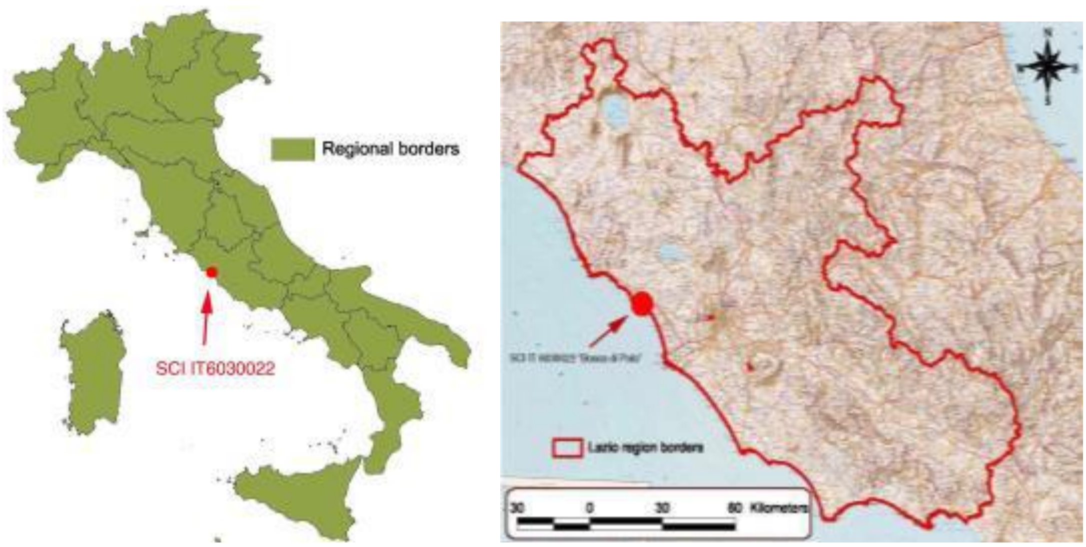
More specifically, the Nestos River arises in Bulgaria and flows into the Thracian Sea, forming the natural boundary between the Regions of Macedonia and Thrace, in northeastern Greece. The Nestos Delta, created by the alluvial deposits of the river that have extended the land into the sea, covers an area of 55,000 ha and is fan-shaped. Its top is at bridge near the village of Toxotes, and its base is the coastal zone opposite of Thassos island. The eastern side of the delta reaches the lagoons of Avdira. On its western side there are nine more lagoons (Vassova, Erateino, Agiasma, Kokkala, Haidefto, Keramoti, Gefyraki, Palaias Koitis of Nestos, and Monastiraki). The lagoons are surrounded by extensive salt marshes and are the most productive fish farms of Greece. The nearest cities are Xanthi 16 km to the east, and Kavala, 25 km to the west. Because of its size and the variety of its habitats, the Nestos Delta is considered among the most important wetlands of Greece and Europe. A significant feature of SCI GR1150010 is the riparian forest known as "Koca Orman" (Great Forest), one of the largest of its type in Mediterranean area. It is noteworthy that the main type of land use in Nestos is agriculture (20%), aquaculture/fisheries (30%), forestry (10%), tourism / recreation (5%) and water management (including watershed management) (50%).

According to the ranking of our country's bio-climate (Mavromatis, 1980), the area belongs to the semi-dry bioclimatic storey with a cold winter and intense mean-Mediterranean character of the bioclimate.



Map 1. Study area in Greece.

Also, the Palo Laziale wood is located along the coastline of the Lazio Region, in the province of Rome, about 40 km NW of Italy's capital, within the territory of the Municipality of Ladispoli. It is set within an entirely fenced-off private property within the SCI IT6030022 “Bosco di Palo Laziale”. It is a flat area of about 50 hectares, with an altitude of between 3 and 10 meters above sea level and about 100 meters far away from the coastline.
According to the bioclimatic features, the area is located within the Mediterranean region, as defined by the compensated summer ombrothermic index (Rivas Martinez, 2008). During the summer, the high temperatures and the low precipitation give rise of a dry period and negative water balance of the soil due to the high evapotranspiration.
The area of greatest naturalistic interest within the SCI is the Wood of Palo in which the actions of the Project are concentrated. It lies in the core of the SCI covering about 50 hectares. It is mainly composed by a planitial oak wood (Habitat 91M0), Mediterranean temporary ponds (Habitat 3170*), and high sclerophyllous maquis as well as a small portion of ″Arborescent Matorral with *Laurus nobilis*″ (Habitat 5230*). A strip of meadow extends for about 18 hectares between the wood and the beach. The remaining part is predominantly affected by strong anthropic use.



Map 2. Study area in Bosco di Palo.

Project objectives

The primary aim of this Project is to improve the conservation status of the habitats included in the Annex II of the Habitat Directive 92/43/EC: (a) 3170* Mediterranean temporary ponds; (b) 91E0* Alluvial forests with *Alnus glutinosa* and *Fraxinus excelsior*; (c) 5230* Arborescent matorral with *Laurus nobilis;* (d) 91M0 Pannonian-Balkanic turkey oak-sessile oak forests, as well as of the species included in the Annex I of the Habitat Directive 92/43/EC: (e) *Eurotestudo hermanni*, (f) *Emys orbicularis*, (g) *Callimorpha (Euplagia) quadripunctaria**, and in the Annex II and III of the Birds Directive 2009/147/EC: (h) *Phasianus colchicus colchicus,* through interventions taking place within the SCI GR1150010 Delta Nestou Kai Limnothalasses Keramotis (Delta of River Nestos) and the SCI IT6030022 (Bosco di Palo Laziale).

The innovative solutions applied and tested during the Project will be actively replicated and transferred to other similar environmental contexts in order to promote and enable the long-term conservation of these habitats and species in the whole Mediterranean coastal area.

The specific objectives of the Project are the following:

- ✓ To quantify the exact causes that have led to the current unfavourable conservation status and to define and implement appropriate and innovative actions capable to restore the affected ecosystems.
- ✓ To develop mechanisms that will ensure the continuation of ecosystem conservation and the management actions even after the end of the Project.
- ✓ To present the outcomes of the Project to the scientific community and to relevant institutions in order to scale-up the restoration, management and valorisation approach in other similar coastal ecosystems of Italy, Greece and Europe.
- ✓ To support the local and regional economy by engaging residents in the Project activities and in the further management and touristic use of the sites.
- ✓ To promote knowledge of the areas, its habitats and species, through outreach and environmental education initiatives.

Expected results

The expected results of the project are described below:

- ✓ Increasing the current surface of the 3170* in the SCI of Palo Laziale up to 0.8 ha and in Nestos Delta by 0.02 ha;
- ✓ Recovering 40 ha of 91M0 of the SCI of Palo Laziale, currently highly degraded, restored;
- ✓ Improving the chemical-physical conditions of the soil in 91M0 (Italy) and 91E0* (Greece), through the provision of water during dry season and the consequent washing out of the substrate sodicity, which is one of the stress factor causing the wood decline;
- ✓ Increasing the population size of *T. hermanni, E. orbicularis, C. quadripunctaria**, *P. colchicus* by improving the conservation status of the SCIs' habitats;
- ✓ Disseminating good-practices on the restoration and management of lowland ecosystems, and mainstreaming the methodological approach of the Sustainable Forest Management Strategic Plan (SFMSP);
- ✓ Involving at least 400 people during the International Workshops that will be organised to scaleup the Project outcomes among the scientific community and relevant institutions across Europe (e.g. managing authorities of Natura 2000 sites, NGOs);
- ✓ Training at least 200 people during tailor-made ToT trainings on conservation engineering (e.g. training on the job to engineering students), restoration ecology, PAs management, EU funding Programmes (e.g. LIFE programme, Interreg, IPA, etc.),

sustainable tourism, sustainable agriculture, with the aim to create new jobs and/or new curricula in the topics targeted by the Project;

- ✓ Engaging at least 2,500 among tourists (local and foreign; "traditional" and cruisers) and residents in the touristic-recreational initiatives facilitated by the Project (e.g. local food festivals and/or markets, guided naturalistic tours, Science and Junior Cafe, etc.);
- ✓ Engaging at least 2,500 people among the local communities in the environmental awareness activities focused on the LIFE programme, Natura 2000 Network and its value for generating incomes, jobs, ecosystem services benefits and quality of life improvements (e.g. guided tours, schools, volunteer campaigns such as Bioblitz, Citizen Science, etc.).

Demonstration character of the Project

A multidisciplinary approach for the conservation of priority habitats and species will be applied to Mediterranean ecosystems. This approach for evaluation and applied conservation actions in such ecosystems will be widely communicated as a good practice. Foresters, biologists, geologists, botanists, zoologists and environmental engineers will be called to apply the latest methods in ecosystem restoration and to adapt them to each concrete case in an innovative and replicable way. The project Actions will utilize scientific and technical knowledge on the restoration of temporary ponds and floodplain woodlands to improve their resilience capacity and to apply adapted management practices. At the same time and in a synergic approach, hydrological works will be implemented, taking into account the restoration and conservation requirements and limiting the environmental factors that produce plant stress conditions. Restoration of adequate hydrologic regime and functions of the habitats will also contribute towards mitigation of climate change effects in the Mediterranean area.

The project will apply and monitor for the first time a process for establishing new temporary ponds, including species reintroduction and management regime, in the ecological conditions and for the temporary pond species assemblages of the specific association of ponds and woodland. The response of these communities to the proposed management measures will be determined through monitoring and management techniques will be further adapted. The results produced will be available to managers of other sites in Greece, Italy and the rest of Europe, demonstrating a process that may be replicated in similar circumstances both in other sites of Greece and Italy, as well as in other Mediterranean countries.

Additional, the project will apply, for the first time in Greece, the method of collecting water during the wet months of the year and then provide them to sustain habitat functions during the dry period, through underground tanks and delivery pipes. The study and implementation methodology, as well as the management of water resources methodology will be demonstrated directly and made available through the project website and social medial to any interested managers of protected areas, related scientists, and other relevant stakeholders in Greece, but also surrounding EU and IPA countries.

The adaptation of the designed management practices according to the results of monitoring and taking into account their cost/efficiency, will demonstrate the optimum way to restore and manage the habitats. This scientific and technical activities carried out during the preliminary, direct and monitoring phases will lead to the definition of good practices that may be applied to other comparable situations regarding the conservation of temporary ponds, floodplain woods, as well as related species of EU interest. Moreover it should be noted the species of the

Mediterranean temporary ponds (3170*) and the species of woodlands (mostly habitat types 91E0* and 91M0), occurring in close spatial and ecological connection, constitute a Mediterranean complex of high ecological value which is at risk, in both Greece and Italy, from a variety of human as well as climate pressures, and so far has been rather neglected in the conservation and restoration efforts. The work that will be carried out through this project will therefore be crucial to identify best practices that are currently limited or even missing for this type of environments, and to demonstrate them to a wide audience.

Figure 1. Temporary ponds (Habitat 3170*) within the Nestos Delta (left figure) and the Palo Laziale Wood (right figure).

Acknowledgments

The PRIMED project ″Restoration, management and valorisation of PRIority habitats of MEDiterranean coastal areas″ LIFE17 NAT/GR/000511, is co-funded by the European Commission under the Nature and Biodiversity component of the LIFE Programme.
